### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### REMINISCENCES OF OLD LONDON—PARKESINE—SWEDISH FILTER PAPER—CHORUS PARTS IN MUSIC.

*Reminiscences of Old London.*—There are many pictorial applications of photography which are peculiarly suitable to the art, and which if properly cultivated would be a great boon to the public. One of these was recently suggested by Mr. Thomas Arches, well known in literary circles as one of the most amiable of journalists. He pointed out what a capital field for photographic illustration the old nooks and corners of London would be, and especially those which are hallowed by cherished reminiscences and which are daily passing from us. Scenes such as these are peculiarly fitted to be depicted in the camera, and the pictures would be almost invaluable to future generations. Discretion would of course be necessary in selecting the proper objects to be photographed and depicting them, so that what is valuable and of interest should not be overlooked; but there are many artistic photographers with antiquarian tastes, who would be thoroughly qualified to do such work. London relies disappear so fast that one would have to be very attentive not to let them disappear unheeded. We do not know whether the "Old Tabard Inn" for instance, has been photographed, but here is a very good illustration of what might be done in securing interesting camera sketches of Old London. Temple Bar will be found missing one of these mornings, as well as its old relative St. John's Gate, Clerkenwell, like many less conspicuous but not less interesting monuments which have been quietly swept away during the last ten or twenty years, to make room for improvements. Reminiscences of old London such as these possess a far wider interest than that felt by the few archaeologists who at the present moment are the only people, apparently, who occupy themselves with these matters.

*Parkesine.*—The compound of collodion and castor oil known as parkesine is still sent into the market in large quantities, and, notwithstanding its rather high cost, is eagerly sought for in the manufacture of many fancy articles. Upwards of one ton a week of the material is prepared by Mr. Daniel Spill, of the Parkesine Company, and this finds a ready sale, the material being employed for purposes similar in character to those for which ebonite or vulcanite is used. We do not know any one who has employed photographic utensils, baths, dishes, trays, and the like prepared from Parkesine, but the light, flexible nature of the compound renders it apparently very suitable for such purposes. Very thin films of the material, of a transparent non-actinic tint, have been suggested for a substitute for orange coloured glass in the dark room, but we do not know if they have been so employed. Nevertheless, photographers do use mixtures of collodion and castor oil—*collodion cuir*—occasionally for printing upon, when a good tough collodio-chloride or some such film is required.

*Swedish Filter Paper.*—A great dearth of Swedish filter paper seems to exist at the present time, much difficulty being experienced in obtaining supplies. Swedish paper of this kind, as many of our readers may know, is far superior for delicate chemical manipulation than the ordinary English description. This is not only of a more open nature, and therefore allows fine impurities to pass through which would be separated by paper of closer texture, such as that made in Sweden specially for the use of chemists; the latter moreover leaves on burning a far less amount of ash, and this is naturally a matter of importance when valuable precipitates are calcined or fused. It seems that there are only one or two firms in Sweden which manufacture this fine paper, and they do so only at certain fixed periods, making at one time sufficient material to last for several years, and it is only when the stock in the hands of the dealers is exhausted that a fresh batch is manufactured.

The date of the last manufacture must have been some time ago, for Swedish filter paper is now scarcely to be met with in London at the present moment.

*Chorus Parts in Music.*—It is surprising that music publishers have as yet in no way availed themselves of the services of photography in reproducing scores. We know that oratorios and operas of a popular nature are published in many editions, the difference in the same being, as a rule, merely in the size of the type. There is, for instance, a large ten shilling edition, full music size, then a two shilling edition, and of most of the popular works there is also a small one shilling edition. Nothing would seem easier, then, than to take photographic lithographs or photo-collotypes of the large edition, on a smaller scale, and thus obviate all the expense of re-writing or re-scoring the whole work. Having only black and white to deal with, there could be no difficulty whatever in the matter, and we think that, well done, the reduced copies by photography would be much clearer than if produced by the hand in a cheap manner. As to chorus parts, supposing each chorister to be supplied with a copy, they need be of very limited dimensions indeed—of the size of a cabinet picture, for instance—and ladies and gentlemen would not then be troubled to hold up a heavy book, or a thin flapping sheet of music, for several hours. Text books of operas, such as are sold at the doors of the theatres, might in like manner contain photographic reductions of the principal portions of the music, which, if clearly printed, might be on a very small scale indeed, and yet perfectly legible.

### AMERICAN CORRESPONDENCE.

#### MEANS OF EXCLUDING CHEMICAL RAYS—AN ERROR AND ITS REMEDY—RETOUCHING AT NIGHT.

*Means of Excluding Chemical Rays.*—It has often been said that photographers work too much in the dark, and the saying is a true one; but the difficulty of obtaining orange glass or tinted paper sufficiently non-actinic for the dark-room window has been the cause. The use of bichromate of potash solution has often been recommended as a substitute for other means, its use allowing much light of a harmless nature to enter the dark room. But the objection to its use again, has been the difficulty of applying it. Mr. J. M. Blake, a valued correspondent, gives me some useful hints on the subject, from which I will make some extracts. He says:—

"Four years' experience in its use has confirmed my first impression as to its utility; but I can now give some further hints that may be useful. My attention was first drawn to the properties of this solution by mention made of it by Mr. B. Ford (see *Photographic News*, 1869, p. 451). He employed the solution, inclosed between two plates of glass, and was thus enabled to watch development through it when out of doors. Soon after I had given the results of some experiments, made to determine the comparative value of this means of illumination, the matter was reduced to practice, and very little modification has since been found necessary in the original arrangement. In the first place, it is well, as involving less trouble and expense, to depend upon yellow paper, as heretofore, for the general lighting of the room—that is, when a window of sufficient size is available—but to have some means of darkening this readily, when danger of fogging is apprehended. Then immediately opposite, and as near as possible to the place it is most convenient to hold the plate while developing, have one or two common cylindrical quart bottles filled with half saturated solution; each should stand upon a small circular shelf with raised edge, placed at the bottom of an opening in a thin board partition. White light should be completely excluded by tacking elastic woollen cloth, so as to press the edge on against each bottle, and also by blacking the bottoms if found necessary. The necks of the bottles should come just inside of the partition, the shelf being inclined for this purpose; thus arranged they can be taken out on cold nights, to avoid freezing. Glycerine or alcohol is not admissible as a preventive; it would reduce the chromic acid. Only solution made from clean crystals should be used. This apparatus will throw a bright light upon an object brought near to it, and its

chief value will be for the critical examination of negatives during and after development. Few will undertake to light the whole room by this means, although it is easy to imagine what a non-actinic paradise is thus brought within the range of possibility.

"In order to make the most of the small aperture that we do use, it is necessary that the light from the sky or snow-covered ground, &c., should not be obstructed from reaching the bottles. It will then pass through from all directions, as through a globe lens, though from an even larger field. The globular form of containing vessel will thus be found superior to the flat, but a cylindrical vessel is cheaper, and more easily replaced, while practice shows it to be little inferior to the globular form. Two one quart bottles of bright glass were found equal to an eighty-ounce thin globular flask eight inches in diameter. The bottles can be placed close to an argand lamp when preparing plates in the evening, and thus a powerful light thrown to a long distance, making drying racks and bath visible with an entirely safe light, while by a near approach a splendid light can be got for development.

"It is well, once in a month or two, to filter the solution, and wipe the inside of the bottles, to remove any deposit that may obstruct the light. Two four-ounce vials filled with nearly saturated solution, gave a splendid illumination inside a tent of the Rouch form; one was placed in the top and received the skylight. When the sun was shining on one of the vials, but screened by tissue paper, a light was obtained that a photographer from habit would instinctively shrink from, but plates were prepared, drained, and developed, quite free from fog. The advantages of having such a light to develop by will strike any one on trial. It often happens, in many mechanical operations, that a workman will accomplish much more work, and do it better, if pains be taken that he has a proper light by which to work. Employers often overlook their own interests by not recognizing this simple fact. Why should this be any the less true in the case of development, an operation requiring great experience and care, and attentive watching? In a proper light, the point where the last portions of clear glass are leaving the shadows, or the first symptoms of fog, can be readily detected. Who cannot recall experience in working in some black hole, where the operations have been pretty much reduced to the game of hit or miss; and you could only know what you had bagged, or what blunders you had failed to commit, on emerging into daylight. This is an extreme case; good work can be done if care is taken to profit by ordinary means of illumination. The use of the light through bichromate of potash solution, it is claimed, will enable us to make still another step in advance.

"And now in regard to the reason of the superiority of this solution: the spectro-scope shows at once. If we start with a very dilute solution, we will see that the transmitted light shows the spectrum in the red and yellow with undiminished brilliancy; while the green, and part way into the blue, are visible to a certain extent. As we increase the strength of the solution the blue is soon cut off entirely, and with a strong solution the portion of the spectrum that contains the active chemical rays is suddenly cut off from the middle of the green, while the red and yellow rays are transmitted with little loss of brilliancy. That portion of the green remaining adds to the illumination, while its chemical activity is almost nothing.

If we compare yellow pot-metal glass, just such as is commonly sold for this purpose, we find the light greatly diminished in the red and yellow, and while the transmitted light is thus robbed of its most valuable part for visual purposes, the spectrum can be traced far into the blue. A specimen of fluted yellow glass was found not to be superior to the other variety.

"There is an orange chrome paper, such as used for envelopes. It may be known by its tinder-like properties, the least spark spreading rapidly on its surface. When this is oiled it gives a splendid orange light, though the spectro-scope reveals blue light, and shows the red and yellow with greatly diminished brilliancy. Then there is the common yellow envelope paper, which fades on the side exposed to light; this is inferior to the orange chrome paper described above. Asphalt varnish is utterly wretched, greatly diminishing the light, and transmitting much blue.

"I have not had an opportunity of comparing the non-actinic muslin and silk advertised in European journals, nor a veritable sample of silver stained glass. Our stockdealers appear to have made no effort to introduce either. Certain varieties of flashed red glass make perhaps the most effective screen known; but there is the drawback, that little light is transmitted, it being only a

part of the red. Full sunlight may be allowed to fall, through a suitably chosen sample, upon a sensitive plate for several seconds without producing fog. Yet by the aid of the spectro-scope and direct sunlight, blue or violet transmitted light can be detected with little difficulty, provided we superpose a piece of green glass to cut off the glare of red light. A blue sun can be seen by simply looking through the red and green glass mentioned, with the addition of a piece of blue glass.

"The utmost amount of light that can be transmitted by any possible medium can of course only approach the amount that falls upon it. If one medium transmits three times as much light as another, and has at the same time the advantage that a sensitive plate can be exposed to its full intensity thirty times as long without producing fog, it is reasonable to conclude that the former is ninety times more efficient. If we reason in this way we may take the above figures as expressing the relation of bichromate solution to yellow glass. If we choose, we can continue to dilute the solution until the same number of seconds' exposure to its full intensity will fog a plate, as when it is closely approached to the yellow glass window. Now our solution will not admit very much more light than it did before, since, when strong, it transmitted the greater part; still there is a marked increase in the light, and it looks so white, that one at first can hardly credit that a plate will stand as good a chance of developing up clear as before the comparatively dark yellow glass window. A landscape was taken in ten minutes through a yellow glass, by means of a portrait lens."

(To be continued.)

## A MONTIE'S TRIP WITH MY CAMERA.

BY REUBEN MITCHELL.\*

AFTER dinner we decided to leave Paris for Rouen by the 7.20 train. My friend having, as usual, settled our account, we had our luggage conveyed to the station, and were soon on our way to Rouen. Darkness coming on soon after we started, I could see very little of the country, but it appeared to be flat and uninteresting, the line running along the side of the river Seine nearly all the way from Paris to Rouen, where we arrived late in the night, had our luggage transferred to a small omnibus, and drove to the Hotel Albion. The inmates had retired to rest, except the night porter, who seemed a very civil and obliging man. We asked for some refreshment, and were informed that there was only bread and butter accessible, and nothing to drink. In a few minutes mine host made his appearance, eyeing us very suspiciously, but supplied our requirements for the time. We were shown to our bed-rooms, which were large, commodious, and comfortable.

The morning after proving sunny, we partook of an excellent breakfast, and engaged a voyageur, and set out in quest of camera subjects. St. Ouen was the first selected—a magnificent Gothic structure, which was commenced in 1318, was twenty-one years building, and was not completed till the beginning of the sixteenth century. This church is one of the finest specimens of Gothic architecture I ever beheld. The summit of the tower is crown-shaped. The ornamentation is exquisitely beautiful, with two towers at the western end, and of very chaste design. The porches or doorways are ornamented with numerous stone sculptures. The proportions and harmony of the whole exterior of so large a building are wonderful, every part richly ornamented and strictly in keeping with pure Gothic. Our admiration was unbounded; but if I dare to suggest a fault, it was that of ornamentation. The limited space for exposing on the south-east side placed us in a difficulty, but my friend got permission for us to place our camera in a window opposite, but as I had only a long-focus doublet at my disposal, I could only take parts, but my friend having a short-focus wide angle doublet, was enabled to get the whole on a 15 by 12 plate. On entering the interior, a thrill of awe and veneration came over me on beholding such a scene of solemn grandeur. The immensity of the building, and of such fine proportions, illuminated by numbers of stained glass windows, three at the east, and one of matchless beauty, the

colours gradually blending with such perfect harmony, render it impossible to describe with the pen; it must be seen to be properly appreciated. There are numbers of very fine windows deserving of notice, also a few paintings; there is also a very fine pulpit of exquisite design and workmanship. To describe this very beautiful church would require a volume to itself to do it justice.

We next visited the venerable Cathedral, a fine relic of Mediæval times, but so surrounded with houses, and the space in front so limited, that it was impossible to get good views. The first Cathedral was struck with the electric fluid in 1117, and in 1200 was destroyed by fire. Jean Sans-Terre, Duke of Normandy and King of England, assigned funds for the reconstruction of the edifice. This immense building, such as we see it at the present day, is the work of several centuries. The fine bas-reliefs in the porches are very much decayed and otherwise injured. The south tower is a very fine piece of work, its height being 230 feet, and it is named the Butter Tower, or Tour de Beurre, because it was erected with the alms of the faithful, who afterwards obtained leave to eat butter in Lent. The whole of the exterior of this old church is most interesting, and of immense size (about 450 English feet in length), and the solemn grandeur is enhanced by the numerous stained glass windows which were, both in design and colour, in perfect harmony. There are twenty-five chapels in the circumference of the Cathedral, wherein are also some good paintings and sculpture, all full of historical interest to the lovers of the antique.

Leaving this old relic, we next visited St. Marlon, another relic of the fifteenth century, and equally interesting, but so surrounded with houses as to make it impossible to take photographs without a number of common shops so close as to spoil it as a picture. The interior is very fine, and will stand favourable comparison with the two preceding ones.

The Palais de Justice is a fine Gothic structure, highly ornamented with all that the architecture of the times possessed in splendour and delicacy. The angular pillars of the piers are covered with canopied statues or small steeples. There are numerous ornaments which surround the windows, and the roofs are all of very elegant design. There is an octangular turret in the middle of the facade. Altogether, the building has a very imposing appearance, but is unfortunately so surrounded with houses and shops that it makes it very difficult to photograph; but we exposed a few plates on the best positions we could get.

Returning to the hotel, we refreshed ourselves, and turned out for exploring. We engaged a voyager, and started for the heights above Rouen to the new Cemetery on the Hill des Sapines. The chapel is built on the highest part of the hill, the situation being very well suited for the purpose; but on coming to the crest of the hill, a most splendid bird's-eye view picture of Rouen bursts on our view. The Seine runs through, with tall, dark poplar trees reflecting their stately forms in the water. There are also groups of building in great variety, mingled with the foliage of numerous fruit and other trees, the distant parts of the town receding into the misty distance. On looking at the beautiful scene before us, we exclaimed, "How grand!" This was the finest panoramic view we saw during our trip. There were several tall chimneys sending forth clouds of smoke, also the iron horse whirling through this fine picture. The beautiful will in course of time have to give place to the useful as the resources of the country are developed.

## ON THE MANUFACTURE OF LIMES FOR THE LANTERN.

BY M. NOTON.\*

This is not a new subject. The most recent information we have upon it is in a communication from Dr. Nicol, of Edinburgh, published in *The British Journal of Photography*, No. 703, page 507.

The instructions therein given, backed by a recommendation of the Editors, and also a famine of limes at home, induced me to try to make a batch. All who use the lime light will admit that it would be a capital thing to be able to keep a stock of limes any length of time without spoiling, and ready for use at long intervals.

Having the requisite materials I took four parts precipitated chalk, and one part of ponderous carbonate of magnesia, both in fine powder, and rubbed them together well in a mortar so as to mix them intimately. Some strong gum water was added, which was not fresh. By this a paste was made. In attempting to roll it into the form of a roller, I certainly managed to do it, but it soon had a flat side. I had used too much gum water, and so made the paste too soft. This was rather a weak point, but it proved the advantage to be gained in knowledge by working a thing out by direct experiment, as I shall show.

Another quantity of chalk and magnesia was mixed, and combined with the paste till it was so dry it would not roll into a long cylinder; this was the other extreme. Some more dry powder was added, till I made the mixture a little dryer than the mixture of chloride of potash and manganese I use for making my oxygen plugs. I soon saw my best plan would be to treat this white mixture in the same way as serve the black one—that is, to ram it into the oxygen-plug mould tube, and make the cylinders that way.

This I did, and it answered so well that I soon used up all the mixture; but there was at present no central hole, and the plugs seemed rather too fragile to stand much handling. They were not so solid as they might or should be; they put me in mind of a brick made of nearly dry clay. I was suspicious of them. They were put aside to dry, slowly first for a day or so, and then transferred to the top shelf of the oven; when nearly dry it was easy to drill holes through them, but they were weak in solidity, and easily broken. Under fire they gave an excellent light, but they gave way, and cracked by the heat where the seams were. More solidity was indispensable, and must be had. The light was encouraging.

Next day another quantity of chalk and magnesia was mixed with fresh gum water, and tempered to a proper state of moisture. A temporary screw-press was rigged up and used. The cylinders made now were without those irregular and unsound layers; they were much more satisfactory up to that point. When partly dried they were drilled, and put into the oven to dry completely as before. Exposed to the oxyhydrogen flame they give a very good light, and do not break down as the others did.

It would be a still greater improvement if the cylinders were made still harder, as they pit more than the caustic limes do; at least I think so. The simple remedy is merely more pressure longer continued.

As to the fall of the limes after exposure, I do not see how they can escape going the way all good limes go. The heat makes the lime caustic, and it is sure to absorb moisture by contact with the atmosphere afterwards. At all events, it is satisfactory to know we can get a good light, and, I think, a better light, for enlargements from the magnesia in them; but time has to prove this.

Since writing the above I have made another batch of plugs; these have been compressed upwards as well as downwards at the same time, and are much better than any of the former ones. Two ounces of chalk and half-an-ounce of magnesia, with two teaspoonsful of gum water, make seven plugs, each one and a-half inch long by thirteen-twentieths of an inch diameter. The quantity of moisture used in them is very small, and they are soon dry.

A larger diameter of cylinder would be an improvement, and discs or cakes may be made to any particular size.

Not having any other moulds, I have been obliged to be content with bringing this small contribution for the information of the members of the Manchester Photographic Society, entirely disclaiming all thoughts of originality.

\* Read before the Manchester Photographic Society.

## ON THE SCIOPTICON FOR ENLARGING.

BY A. BROTHERS, F.R.A.S.\*

An artificial light suitable for enlarging photographs has long been a desideratum amongst photographers. The oxyhydrogen light is used successfully; but the trouble of making the gases has always been a serious inconvenience. The electric light is, perhaps, the most suitable; but the inconvenience attending its use is greater than in any other kind of artificial light, and tends to restrict its application in photography.

The magnesium light at one time promised to be of the greatest service to photographers, and it is, no doubt, one of the simplest forms of artificial light. There are objections to its use, and chiefly that of the expense of the magnesium and the necessary apparatus; the brilliancy of the light is only surpassed by the electric light. The magnesium light has this advantage over all other kinds, that it is very portable, and can be used in cases—such as the illumination of interiors—when no other artificial light could so conveniently be used. It is also very useful in portraiture, as some of the most artistic effects may be obtained by its use.

But I am chiefly concerned this evening in directing your attention to a new form of apparatus for enlarging. The cost of the apparatus has hitherto been the chief objection to the use of any kind of artificial light for enlarging photographs; but this objection can be said no longer to exist, as the sciopticon will be found to be one of the cheapest and handiest of instruments yet introduced. You have all seen what this little instrument will do when used as a magic lantern. I have now the pleasure to exhibit two enlargements made with it.

It is unnecessary to describe the proper arrangements for working an enlarged negative, as every one here must be fully cognisant of all that is required. I have only to add that the exposure was one minute; and at this season of the year—in the ordinary light of a December day—the exposure would have been about the same.

## NOTES ON PHOTO-COLLOTYPE PRINTING.

BY CAPTAIN J. WATERHOUSE, ASSISTANT SURVEYOR-GENERAL OF INDIA.†

In continuation of my former paper on this subject, read before the Society in June last, I have to communicate some additional notes regarding the process which may be of interest.

*Use of citric acid as a clearing agent.*—In my former paper I gave a list of substances that seemed to have a clearing action on photo-collotype films. As citric acid appeared to be in some respects the most likely to give good results, I have tried it on several occasions, and found it most efficient for clearing up a dirty plate, and putting it into good printing condition, without doing any injury to the surface of the film. It seems to possess in itself the useful properties of cyanide of potassium and nitric acid in freeing the surface from greasy scum, and at the same time making the lines take the ink well. I have not yet settled the best strength of the acid, but have generally used it at about 20 per cent. The accompanying specimens will give an idea of its effect. At present it has only been tried for line-work, in which the absolute cleanness of the ground is essential to satisfactory results; but it would probably also be found of service in printing half-tone subjects.

In some cases it is possible that lemon-juice might be

substituted for the more expensive citric acid; but I have not yet tried it.

*Transferring the negative on to the sensitive printing plate.*—In copying maps or other fine-line subjects, it is impossible to obtain good results unless the negative and the surface of the printing plate are in absolutely perfect contact; and although sufficiently good contact may sometimes be obtained by merely placing the two plates together in the ordinary way, it is by no means a certainty, on account of the difficulty of avoiding slight inequalities on the surface of the printing film or the negative; and after many failures from this cause, especially with transferred negatives, an attempt was made to ascertain whether it would not be possible to transfer the negative on to the printing plate, so that it might be in the most perfect contact with it during the exposure to light, and afterwards be removed without damage, and be fit for use again. After several trials, in which the only difficulty experienced was in the removal of the thin collodion films after exposure, the following method was found to give satisfactory results.

The negative is prepared for transferring by coating with india-rubber solution and transfer collodion in the usual way. The sensitized and dried gelatine surface of the printing plate is covered with an extremely thin coating of wax dissolved in turpentine or benzole, applied in the same manner as in waxing glass plates, from which a gelatine film is to be stripped. The plate is then placed in a dish containing sufficient strong spirit of wine to cover it. The thin negative film, having been removed from its glass support, is laid down upon the gelatine surface in its proper position; the plate is then removed from the spirit, and the collodion film, having been pressed into close contact with the gelatine by means of the squeegee, is covered with a few thicknesses of blotting-paper under a thick glass plate, and allowed to dry. When dry, any stopping out that may be necessary can easily be done on the negative, and the plate is ready for exposure. The collodion tissue may be removed immediately after exposure to light, or after sunning. If the gelatine surface is well coated with wax, and the negative tissue tolerably tough, there is no difficulty in removing the film, which may then be laid aside between sheets of blotting-paper for future use. Should the film tear or be difficult to remove, it should be dissolved off at once with ether or other solvent; otherwise, if left to soak in water, there will be a continuing action of light in the parts protected by the film, so that they will print darker than the other parts of the plate, and spoil the impressions.

Before the printing films are put to soak the wax should be removed with a little turpentine.

Negative films strengthened with a coating of gelatine may also be transferred in the same manner; and in an experiment tried with such a tissue, it was found that there was no difficulty in removing it from the plate, even without the preliminary coating of wax.

The object of effecting the transfer in a bath of spirit of wine is, that neither the gelatine nor the bichromate of potash are dissolved by it. The spirit may be used over and over again.

The same method may be applied very advantageously in processes of photo-lithography and photo-engraving where it is desired to secure the utmost possible sharpness in printing from reversed negatives direct upon the stone or metal plate, which is generally a matter of some difficulty when using glass negatives.

The only objections to the method are the slight extra trouble and expense and the risk of destroying the negative; but in cases where a negative can be replaced if destroyed, these defects are of little moment compared to the advantages gained by being able to secure successful results with comparative certainty.

\* Read before the Manchester Photographic Society.

† Read before the Photographic Society of London.

*Continuing Action of Light.*—In the course of the above experiments I obtained more than once an unexpected confirmation of Captain Abney's observations on the continuing action of light. The negative film having torn whilst being removed after exposure, fragments of it were left on various parts of the plate. It did not occur to me at first to use a solvent, and the plate was left to soak so that the gelatine might be softened and the pieces of film removed. This was done with some difficulty, after a soaking of several hours' duration; and, after a further washing to remove all the remaining bichromate, an impression of the plate was pulled, when it was found that the parts protected by the film from the action of the water printed up quite dark; and though the plate was afterwards dried, and the whole gelatine surface evenly and equally soaked again, the dark stains still remained, showing that they must have been due to a decomposing action set up by light, and continuing after the plate had been removed from the pressure frame.

*Action of Cyanide of Potassium followed by Citric Acid.*—The stains just mentioned were entirely removed from one of the plates by means of cyanide of potassium; but it was found that the detail had suffered also, and could not be printed up. The citric acid solution was then applied, and on pulling another impression the lost details re-appeared in all their proper force, but there were no traces of the stain. This affords a good exemplification of the action of these agents, and their value in printing from dirty plates.

*Alteration in Formula.*—I have lately been trying a modification in the formula of the tanno-gelatine composition used for the printing plates, and it now stands as follows:—

Gelatine	...	...	...	...	50 parts
Albumen	...	...	...	...	30 "
Tannin	...	...	...	...	1 part
Water	...	...	...	...	240 parts

The addition of albumen seems to be advantageous in rendering the film tough, and making it more adherent to the glass.

The new composition seems to give better results for half-tone subjects than my first formula, while it is equally good for line-work.

M. DE CONSTANT ON DRY PLATES.\*

*Drying the Plates.*—In general, the plates to be dried are put into a closed box, in a corner of the dark room, and a warm water bottle is put inside to assist the desiccation. There are, however, several elements of danger in this plan of proceeding, such as:

1. If one is not careful to change once or twice the blotting-paper upon which the plate stands, there is formed at the foot of each glass an accumulation of liquid more or less contaminated by the paper, and this is drawn up again to the surface of the plate, which is almost dry, producing spots and blemishes of various kinds, generally elliptic in form, which blacken on the development of the plate, and damage the cliché.
2. The source of heat introduced into a box of limited dimensions being very close to the glass causes the desiccation of the plates to proceed irregularly.
3. The box being closed, the moisture which disengages from the plates in drying remains imprisoned, and, joined to that accumulating in the box when placed on the ground, prevents the plates from becoming completely dry.
4. Finally, a closed box, especially if it is situated on the

floor, always preserves in its interior a temperature sensibly different to that of the room, so that when the plates are put into the dark slide, the difference in the temperature of the atmosphere produces upon the plate a vapour scarcely visible to the eye, but which is not less persistent and dangerous, for if the plate is put into the camera in this state, the vapour enclosed will be maintained, and will cause, as I have often remarked, very great insensitiveness, the reason of which it is difficult to trace.

To remedy all these inconveniences which long experience has caused me to become acquainted with, I have adopted the arrangement which I will now describe.

The plates, put on end, as I have said, upon blotting-paper to drain after the preservative has been applied, is next placed in a special cupboard, where it reposes upon a support constructed simply of a stick cut to an acute angle. Lightly supported by one of the upper angles against the end of the cupboard, the plate is sustained at the back by long pegs projecting from the wall of the cupboard at four inches apart. The plate therefore remains perfectly isolated, it having air space on all sides, and the moisture which is at the foot of the plate upon the angular stick is in no way arrested, and may drop or be absorbed by the blotting-paper at the bottom, which is replaced from time to time.

When the cupboard is closed (all the plates being properly arranged), a practical shutter in the door is opened, the aperture of which is covered with yellow tannin to prevent the ingress of light. This opening allows for the exit of the moisture, and establishes good equilibrium with the atmosphere of the room, which it is well to warm moderately if the weather is moist or cold. The plates are thus dried gently, uniformly, and completely, and no vexations change takes place when they are put into the dark slide. Nevertheless, a plate should never be exposed in the camera before an attentive examination of the film has taken place, which should be regarded by reflected light. If the plate appears brilliant like glass, and, viewed as a transparency, it does not exhibit spots, nor marble markings, nor inequalities, one may have confidence in it, and put it into the dark slide. If, however, it has a cloudy aspect, it should be put face to face with a hot iron, or held near a stove until this appearance vanishes, and its brilliancy re-appears.

I have already said that dry plates possess the inconvenience of becoming transparent, so that when the light passes, an effect termed blurring is produced, to remedy which it is usual to back the plate with some colour of a sombre nature, a most laborious proceeding.

I believe that with albumen in conjunction with the caramel it is possible to prevent the reflections in question, taking care to apply against the back of the glass in the frame a sheet of matt black paper.

As to the keeping qualities of the dry plates prepared by this process, I think they will be found excellent, although I have not much practical experience on this point beyond the period of a month; but I cannot repeat too often that their preservation in good condition depends very much upon the preparation, as also upon the mode of desiccation adopted.

(To be continued.)

ONE PRINT FROM TWO NEGATIVES.—Mr. Kirk, the patentee in the United States of a method of producing a negative at the front and at the back of the plate in one exposure, with a view to produce soft prints, is offering to American photographers the right to use his patent process free of charge for six months. If at the expiration of that time they wish to continue its use, a sum of fifty dollars, or round numbers £10, will be charged for the license to use the method.

## THE PAST YEAR.

In glancing at the photographic history of the past year, it is satisfactory to find that, besides the somewhat intangible, however real, progress which may be comprised in general improvement, we have two or three very definite gains during the year, both in knowledge and power, and of a very practical character. For many years the photographer's knowledge of the chemical action of light has advanced but little. In the early years of the art the late Sir John Herschel arrived at the conclusion that the whole of the solar rays possessed actinic power, instead of a portion only, a conclusion confirmed by the research of some other physicists at the time. The recent interesting investigations of Dr. Draper, recorded in our last volume, have more definitely established this view, and the still more important discovery of Dr. Vogel, whereby a film of bromide of silver may be made as sensitive to the yellow ray as to blue, at once illustrates and gives a practical value to the conclusion to which we have referred. The fresh ground thus broken, in relation to actino-chemistry, presents ample field for interesting experiment, and a promise of considerably extended range in photographic power.

Few discoveries, of a purely practical kind, possess more importance than that published by Col. Stuart Wortley, as to the action of an enormously powerful alkaline developer. In the first steps in alkaline development by Mr. Leahy, ammonia alone was found to act as a developer; but the tendency of experiment since that time has been to use the alkali very sparingly as an adjunct to pyrogallie acid. Col. Wortley has discovered, however, that an eighty-grain solution of carbonate of ammonia, with a mere trace of pyrogallie acid, may be used with success, and kept perfectly under control. It has long been held by theorists that exposures might be greatly shortened if a method of using various powerful developing agents at hand, without risk of fog, could be devised. This, in relation to certain dry processes, Col. Wortley has done: how far the principle can be extended remains to be ascertained. Mr. R. Manners Gordon finds that this developer, applied to gum-gallie plates, permits an exposure not exceeding that of wet plates in their most sensitive condition. Col. Wortley finds the same rapidity with this developer when applied to his dry emulsion plates; and, in addition, a degree of vigour in the negatives not otherwise attainable without much longer exposure. How far such a developer may succeed with wet plates, we are uncertain; but it seems probable that, with wet bromide of silver films, it should work without difficulty.

With the exception of this important novelty in development, there has been but little change made in dry-plate work. Emulsion processes have received considerable attention, and progress, in securing satisfactory conditions, has been made. A series of instantaneous views by Col. Wortley, taken under all the difficulties of exposure involved in working aboard a yacht in full sail, attest the rapidity which has been attained. Some attention has been given during the past year to the use of gelatine as a vehicle for bromide emulsions. Some years ago a similar attempt was made to employ gelatine as a vehicle for chloride of silver emulsions; but whilst some fine results were obtained, from a variety of practical difficulties, and the absence of any specific advantage, gelatino-chloride of silver did not supersede collodio-chloride of silver. At present it would be premature to predict the future of gelatino-bromide of silver emulsions. Mr. Burgess and others have produced good results by means of formulæ not at present made public; but whether in the main the balance of advantages or difficulties will prevail is uncertain.

In the wet process there has been but little change. Mr. Black's nitric acid bath, and Elbert Anderson's weak baths and highly-salted collodion, have been discussed; but general practice remains unchanged. A moist process for portraiture, in which the preservative is also the developer, has been tried, and, so far as we know from the meagre details yet disclosed, with some success. Col. Wortley informs us that, acting on the suggestion of an article we published some time ago on the restraining powers of viscous substances, he added such a body to an alkaline developer, and applied it to an emulsion plate at the time of preparation. The plate so treated remained without any tendency to reduction until exposed to light, when it was at once initiated, so that development commenced in the camera immediately on commencing exposure, and was gradually completed without further application of a developer. Such a process seems to promise many advantages. The addition of nitrate of baryta to the silver bath, proposed at the South London Society by Mr. Henderson as possessing many advantages, chief of which is the maintenance in solution of iodide of silver, and consequent prevention of pinholes, has received some discussion. It is, undoubtedly, worthy of a trial, as is also the suggestion of Mr. Chisholm, an American photographer, to get rid of pinholes by adding a few drops of hydrochloric acid to the nitrate bath.

The admission to the sensitive surface of a certain amount of diffused light, white or coloured, as an accelerating agent, has received some further attention in this country and in America, and the reports are generally in its favour. Curiously enough, whilst all photographers are anxious for means of securing rapid exposures, this method, which is simple and easy, and is recommended by good credentials, receives but little attention or experiment. It is well worth more consideration.

Silver printing remains unchanged, both in practice and results. The plan proposed in our pages twelve months ago, of preserving the sensitive paper between sheets of bibulous paper which had been previously saturated with a solution of carbonate of soda, has been extensively applied with great success, a modification communicated to our readers by Mr. W. Bedford having been found very useful by many. Absolute stability is still a desideratum. The method of securing permanency by fixing in the dark, and placing each print in a fresh solution of hyposulphate of soda, proposed at the Photographic Society by Dr. Gayer, was suggestive. The tendency of such a proposal was doubtless desirable, and would probably induce renewed care in this direction, even where it did not secure literal adhesion to the advice.

Portraiture has been steadily growing in general excellence; but there has been little of a specially novel kind introduced, especially in this country. On the Continent

and in America efforts to secure softness by some mechanical method, and so to ameliorate the mercilessly sharp rendering of coarse texture or other natural defects, have been very prevalent. The free use of shadow, and the aim to secure transparency in that shadow, which distinguish the style of portraiture recognized as "Rembrandtesque," has been adopted by many portraitists. Modes of securing softened definition have abounded. M. Denier, of St. Petersburg, introduced some pleasing examples of this softened definition, which was said to reduce the necessity for retouching to a minimum, and offered to sell the secret method for a consideration, and photographers have been stimulated to imitate the results. Printing through a medium, in the manner employed by Carl Meinerth, has been tried. The method of printing from two similar negatives, one superposed upon the other, has been again revived, and various modes of securing the negatives have been described in our pages. A printing-frame has been devised by Mr. Jacoby, in America, to permit destroying the contact between the print and the negative during a portion of the printing exposure, so that, being partly impressed whilst in close contact, and so a certain amount of sharp definition obtained, the remaining portion of the printing should be effected without close contact between the print and negative, so that diffused definition should result. Another plan, proposed with a similar object, consists in commencing the exposure of the sensitive plate with a stop to secure sharp definition, and removing the stop during exposure, so as to introduce the spherical aberration due to the use of the full aperture of the lens. These, and some other methods with a similar aim, have been tried abroad, with a greater or less amount of success, and have indicated an extended taste for some modification of the uncompromising literal rendering of lines, freckles, and coarse texture at one time regarded as a technical excellence in photography. As a rule, portraitists in this country object to anything like fuzziness in definition, and these methods have only been received with partial favour by English portraitists.

In few practical operations has greater progress been made than in enlarging processes, and a degree of excellence has been attained hitherto almost unknown. The most successful methods seem to be those in which a perfect transparency is obtained from the negative, and from this transparency a large negative. A little judicious touching at each stage of the operation is singularly valuable in giving a perfect result, with but little risk or necessity of injuring the likeness by over-touching. Mr. Croughton's recent paper gives some valuable hints on the subject.

The production of photo-enamels has progressed during the year, but not largely. The number of photographers producing fine results has increased. As regards excellence of result, little has been left to desire in work already produced; but there is room for more extended practice of this very beautiful and in every way desirable branch of the art.

Permanent printing processes generally have not received much attention. The carbon process is still chiefly confined in practice to the Autotype Company, in whose hands it seems to have attained practical perfection. The late M. Marion introduced two ingenious processes, which were duly described in our columns, but which have not yet been much adopted. Improvements in photo-colligraphy have been also described in our pages from time to time, chiefly by Captain Waterhouse and by Captain Abney. A valuable and novel process, entitled Photopapypotype, has been patented by Captain Abney, and an improved method of producing a photo-lithographic transfer, devised by Mr. Walter Paul, was brought before our readers early in the year. In some photo-mechanical processes a degree of excellence, scarcely falling short of that of silver printing, has been attained; we may name especially some of the photo-colligraphic processes and the

photo-relief process: a very charming example of the latter will be found in our YEAR-BOOK just issued.

The experiment of producing direct in the camera very large heads, for which Mr. Crawshaw instituted a competition, was so far successful that it will be repeated, a series of similar prizes being already announced by the munificent donor of the last.

Photographic Societies have not undergone much change during the year. None having an active existence have gone out during the year, and no new ones have been initiated. All which have survived their youth appear to be healthy and active. The Photographic Society of London, after some years of struggle, having attained again a flourishing and successful position, is at this moment threatened with some trifling internal commotion, probably of the kind which, in vigorous physical constitutions, is occasionally styled a "healthy eruption," possibly wholesome, rarely pleasant. Some further effort has been made by a few earnest working photographers to establish a Benevolent Society, for the benefit of the unfortunate and needy amongst their body, with, we hope, a prospect of a successful issue.

#### SIMPLE ARTIFICIAL LIGHT FOR TRANSPARENCIES AND ENLARGING.

EVERY facility which makes some branch of photography, whether for pleasure or business, independent of sunlight, during the gloomy months which prevail in this favoured land, must be regarded as an undoubted boon to the photographer. The electric light is cumbersome and costly; the oxyhydrogen light is cumbersome, and not free from risk; the magnesium light is a capital aid, not cumbersome, and for professional purposes not relatively costly, but still sufficiently costly to deter the amateurs and small photographers who may require its aid only under occasional circumstances. For printing transparencies by contact, a gas flame or that of a paraffin lamp is sufficient; but printing transparencies, however interesting, is not an occupation which can last for ever. A light easy to obtain, easy to manage, sufficiently bright to permit of various camera operations, such as reproducing negatives as well as transparencies, either the same size, enlarged, or reduced as may be required, and we have concurrent testimony at the same moment to the value of the same lamp for the purposes in question.

In our YEAR-BOOK, just issued, we refer to the *Sciopticon* as presenting a probable means of producing enlargements with little trouble, and in the same annual we give Dr. Liesegang's experience with Marcey's *Sciopticon*, which is the prototype of that patented by Mr. Woodbury in this country, in this very direction. At the last meeting of the Manchester Photographic Society, Mr. Brothers read a paper on the same subject. The time of exposure was stated to be one minute, and we are further informed that this was about the same time which would have been required by the ordinary daylight of this dull season. The precise amount of enlargement, or the lens and aperture used, are not stated; but these are details which each operator would soon determine for himself by experiment. Some years ago a correspondent gave us some details of successful enlarging operations, conducted with an ordinary hall lamp, burning paraffin, and an ordinary magic lantern. With this arrangement he was enabled to produce transparencies, enlarged from a card size to twelve by ten, with an exposure of seven or eight minutes. As the estimated illuminating power of the *Sciopticon* is three or four times that of an ordinary lantern, a similar result should be produced by the aid of the former by an exposure of little more than two minutes. For producing life-size heads from card negatives, Dr. Liesegang finds the exposure varies from three to five minutes.

The advantages to be gained by the use of an artificial light, as compared to the dull and varying daylight of an

English winter, consist, however, in increased certainty. Nothing is more difficult than to guess the actual value of a dull winter light, modified, as it generally is, by a certain amount of fog or vapour. An artificial light, on the other hand, is constant, and however other conditions may vary, such as amount of enlargement, degree of intensity in the negative, condition of chemicals, the light may be regarded as a fixed quantity. We remember a gentleman, who was engaged in producing enamels, once remarking to us that the most troublesome part of the operation was securing transparencies of the precise quality necessary for a perfect result, which the varying light of winter made almost impossible until he began to use the magnesium light, which reduced exposure to a certainty. It was reduced simply to the burning of so many feet of magnesium ribbon. In like manner, with a lamp like the Sciopticon, the exposure is reduced to the burning for so many seconds of a constant light, which, once ascertained for a given series of conditions, will always remain the same for similar conditions, and the requisite modification may be easily calculated for varying conditions. Hence it seems that for producing collodion transfers, photo-crayons, lantern and stereo transparencies, enamels, enlarged negatives, and such work generally, a boon is promised to photographers which has long been desired. As a paraffin flame, under its best conditions, has, of course, a much more yellow tint than sunlight, there may be room for considerable modification of the character of the sensitive film best suited to such a light, a free use of bromide being probably desirable. But this is a matter for experimental investigation.

The value of the Sciopticon for lantern purposes proper do not require stating here.

#### A RAPID COFFEE AND ALBUMEN PROCESS.

Mr. T. C. Roche describes a dry process, which is, as he states, in skilled hands, as rapid as wet collodion. We condense details from *Anthony's Bulletin*. The plates receive a preliminary coating of dilute albumen, similar to that now commonly used in the wet process. A bromo-iodized collodion and ordinary silver bath are employed. The excited plates, having been well washed under a tap with soft water, are covered with the following preservative, which is suffered to flow well over the plate twice, and then allowed to dry spontaneously:—

The preservative consists of—

White of one egg.	
Water ... ..	1 ounce.
Liquid ammonia ... ..	15 drops.

Beat up well and mix with four ounces of plain coffee solution (one large tablespoonful of Java coffee and five ounces of water), letting it boil well. When cold filter twice."

The author says:

"Expose the same as any good wet plate for plenty of detail, or it would be better for those who are not used to working dry plates to give twice the time. Develop the same day, or keep the plates for two or three days if desired. To develop, wet the surface of the plate well under the tap; then flow on a weak solution of alcohol and water, and drain; then flow on the developing solution No. 1, working it well over the plate; drain back into the developing glass and add No. 2. Now flow the solution on the plate again, and the picture will appear. As soon as all the detail is out, wash the plate well with water; then flow on a solution of—

Acetic acid... ..	1 ounce.
Water ... ..	6 ounces.

Work well on the plate to neutralize the alkaline developer. Wash off, and then strengthen in the usual way with acid pyro. and silver. The more silver used the harder the negative will be. Fix in hypo.

#### "Alkaline Developer."

No. 1. Pyrogallic acid...	96 grains.
Alcohol ... ..	1 ounce.
No. 2. Water ... ..	3½ "
Aqua am. ... ..	½ "
Bromide potass ... ..	40 grains.

Dissolve the bromide first in water, and then add the ammonia.

"To develop, take one ounce of water, adding 15 drops of No. 1; flow on the plate as above; then pour back into the glass and add 50 drops of No. 2. Pour on again, and the picture will flash out immediately."

The author gives an additional formula for alkaline developer, which may be used if the operator prefer. Whatever alkaline developer be used, he prefers stopping as soon as detail appears, and strengthening with pyro. and silver.

#### SENSITIZING, DRYING, AND FUMING PRESS.

BY J. G. TUNNY.

IN my holiday rambles last summer through Scotland and England, and looking in here and there on my professional friends, I was surprised to find so many still wasting time and material by sensitizing their paper in quarter sheets. The want of convenience for sensitizing the full size of sheet was the general reason for still adhering to the primitive mode.

The annexed drawing shows a press I have devised for

successfully overcoming many of the inconveniences arising from want of room for carrying on the preparation of the sensitive paper. The press is made of 3/4-inch yellow pine, the entire height from E to F being 59 1/2 inches, and the depth (C to C) 31 inches. From A to A is 26 1/2 inches, having at B to B and D to D a depth of 12 inches. I I are two fillets upon which the baths lie for the suspension of the paper. The laths should be about 1 inch by 1/2 inch, with two small tapered knobs about 2 inches from each end to keep the paper from coming into contact while drying. Into each lath put two silver pins about 20 inches apart (a little bit of silver wire brought to a point by a file answers the purpose best, but let the wires have a slight bend upward, to prevent the paper falling off); the bath K, lying right in front of the recess. The paper, when lifted and drawn over the glass rod in front, is attached to the lath lying on the fillet I I. Another sheet is laid down; and when ready for lifting, push the first lath back and place another lath for the suspension of the second sheet, and so on

until the recess is filled, which will contain seven sheets of paper. About 9 inches below the paper there is a centre bottom of sheet iron perforated round the edges, under which Bunsen burner L is lighted, and in about ten minutes the seven sheets are dry. The Bunsen being lowered to the lowest possible flame, a saucer containing about  $\frac{1}{2}$  ounce of strong liquid ammonia is placed upon the centre of the sheet iron bottom, care being taken that all the sheets are free from each other, and a door, around whose edges a double thickness of velvet has been glued, is tightly pressed in front of the paper, entirely preventing the escape of the ammonia vapour; and the fuming takes about ten minutes, more or less, according to the strength of the liquid.

The bath is made of yellow pine dovetailed and put together with marine glue: the bottom is fitted in like a panel. When the wood is thoroughly dry, let it be coated with a solution of paraffine, dissolving about 3 ounces in 4 ounces of benzole, repeat this coating three or four times, both outside and inside, and the bath will be found to be light, and much easier to handle than those of glass or Wedgwood ware. Beneath where the bath stands there are two drawers with flap door, each capable of holding a ream of paper, and a nice-fitting lid prevents the bath getting dust; but it is best to return the solution to a Winchester bottle kept always filled to the neck. This prevents the necessity of filtering, and is consequently a great saving.

### THE LIMIT OF RETOUCHING.

BY ROBERT TAULKNER.

The legitimate plea for retouching is based upon the limited capacity of photography. Inasmuch as the beautiful, luminous, and warm shadows we see in nature are reproduced by photography as blacks, it is perfectly legitimate by means of retouching to veil this blackness; the high lights may be strengthened, and the spots, freckles, and defects of manipulation may be softened or removed; beyond this is a violation of truth.

At the last exhibition of the Photographic Society many photographs and enlargements might have been pointed out in which all the endless variety of texture, form, light and shadow, to be found in nature were ruthlessly destroyed; all the pulp and suppleness of flesh removed, all character and expression blotted out, until the effect of a soulless China mask had been obtained.

An important enlargement, a lady's portrait, was especially untruthful, the greater part of the face being in shadow; that portion which was light was placed in contact with a dark background, and appeared as hard and unvaried as a white line ruled by machinery on a black ground would be. It should be remembered that under these circumstances photography would always give a much harder outline than is found in nature; and, therefore, the utmost care should be taken to preserve all those indications of form of which the outline of a face is full, also refined and subtle, and each having its light and shadow. Even spots and freckles may be allowed to remain, because they would in all probability help to round off the outlines; and the background ought certainly to be varied and lighter where it comes in contact with the face. Often in the works of great painters a double outline may be traced, made by the dark transparent colour used for finishing the background being taken up to the outline only here and there; and in some places it is left by a crisp touch, which gives great spirit and animation. It must be observed here that there is no such thing as an outline in nature; it is merely an expression. To do as little as possible, and to know where to leave off, ought to be the aim and study of the retoucher. He is the prince of artists and of men who knows when his work is done. On this Appelles founded his superiority over his contemporaries, &c., &c., *Fuseli, 130th Aphorism*. The sacrifice of the essentials of art for its refinements and puerilities has, in all ages, caused the destruction of schools of painting; and excessive retouching will,

in like manner, destroy all the value of photography. "Truth above all things," should be the motto of all followers of photography, for the art is valuable only so far as it is truthful. As a noble example of untouched photography, I would draw attention to the portrait of Sir Henry Taylor, by Mrs. Cameron. In this picture the man lives and thinks. It is great in style and unconventional in treatment, and possesses the rare quality of action in repose; the modelling is excellent; every line of thought and suffering is well expressed, but not obtrusively so. Place the negative from which this picture was produced in the hands of a tasteless, soulless retoucher, and to what a vapid, expressionless thing he would reduce it, especially if instructed to give it the *Berlin Finish*? What a priceless possession an untouched photograph of Shakespeare would be! How unsatisfactory and tantalising a retouched one! Again: how precious to the bereaved is the faithful image of a lost friend, or a dear relative; remove expression, character, or even peculiarity, and how little comfort such a remembrance would bring! The mourning survivor looks upon the shadowed picture of the beloved one; he searches for the familiar lines of thought or age, the marked and decided feature, the pronounced characteristic. Too often he seeks in vain—all is smooth and pretty, meaningless and vapid; for the vigorous portrait painted by the honest sunlight has been submitted to the tender mercies of the Retoucher!

### FRENCH CORRESPONDENCE.

THE readers of the PHOTOGRAPHIC NEWS most likely remember the plan adopted by M. Melchion, a skilful photographer of Marseilles, for reducing the period of exposure which I mentioned in one of my recent letters. M. Melchion, after having placed the slide containing the sensitive plate in the camera, covers the front of the lens with a piece of ground glass, the rough surface towards the lens, and exposes the plate for one or two seconds, according to the nature of the light. This done he takes away the ground glass and proceeds to take a photograph of the object in the ordinary manner; only, thanks to the impression already made by the light upon the film, this exposure need only be of very brief duration.

Many photographers have essayed this very simple method, which succeeds very well, supposing the dark slide used is of a suitable nature. To overcome any difficulty that may arise in this respect, an experimenter has suggested a modification of M. Melchion's mode of proceeding. He has two caps, the one of ground glass surrounded with a zinc or copper ring to fit on to the lens, the other, to fit upon this, of cardboard, which is easily fitted and unfitted. The mode of operating is to pose the model, then cover up the lens with the double cap, put in the dark slide, open the shutter, take off the opaque cap for a second or two so as to give a little exposure through the ground glass, cover the lens again, and then take off the double cap, exposing the plate to the object as long as may be deemed necessary, and then finally capping the lens again. In this way it is possible, as M. Melchion explains, to reduce materially the period of exposure in portrait photography.

Another correspondent communicates to me a modification which he has recently made to the wet collodio-bromide process of Mr. Sutton. The film, covered with a hygroscopic preservative, will keep in a moist state during the whole of the day. The film remains very sensitive, and the *cliches* are of a most delicate nature. Finding, however, the developers proposed to be slow, my correspondent proceeds in the manner following:

After the plate has been silvered in a ten per cent. bath, and has been exposed and well washed, it is allowed to drain for a minute, and is then flooded with, or put into a four per cent. solution of silver, before the developer is applied. It remains in this silver bath for about half a minute, and the image is then simply developed with sulphate of iron.

The image under these circumstances appears at once, and gradually progresses. If the bath is stronger, the blacks become too intense and opaque, and yield too hard negatives afterwards.

A little while back I expressed the conviction that the production of silver prints had almost run its course, and that the introduction of permanent printing, universally, was rapidly approaching. Every day appears to confirm this opinion. On the Boulevards and in the Rue Rivoli, the public may be seen standing around the printsellers' shops, attracted by two figures of a highly artistic character exposed in the windows. The one represents Lorraine, the other Alsace, and they are two peasant girls in their simple national costumes, the charm of the models being heightened by their elegant and sympathetic expression. The pictures are the production of M. Braun, of Dornach, who is distinguished as one of the most happy composers of art studies.

These two studies, of which several thousand copies have been sold, are printed in carbon. On visiting the establishment of MM. Pierson et Braun fils, I was able to inspect a perfect gallery of photographs all of which are likewise produced in permanent pigments. The firm, or I should say rather, the manufactory, at Dornach, sends to the Paris house supplies of pigmented paper, and this is sensitized as required at Paris, the sheets being of colossal dimensions. Negatives measuring ninety centimetres in length are printed, as shown at the last meeting of the French Photographic Society. These large reproductions of paintings in the gallery of the Louvre are not the only objects produced by M. Braun. He has reproduced them on a small scale also, and in this way has formed a most interesting collection. He also makes reproductions upon canvas, the images being transferred to that material when printed. These outlines, which could not be produced so well and faithfully by any other means, are confided to competent artists, and *fit similes* of the original paintings in the Louvre are prepared. Already a large number of such copies have been painted in this way, and a large number are now on show at the gallery of MM. Pierson et Braun, forming, as it were, the museum of the Louvre in miniature. On the walls there are to be found specimens of every school and every master, and how much the collection has already cost can scarcely be estimated. Payment has already been made to painters to the amount of 60,000 francs in producing these works, but as purchasers have not been wanting ever since the establishment has been opened, there can be no doubt that M. Braun will very speedily get back his money.

As a matter of course a process which is so suitable for the reproduction of paintings is also equally applicable to portraiture taken from life. The same mode of production is followed in the case of all painted portraits that issue from the firm of which we speak. Very soon we shall have no other portraits printed but in permanent pigment. I have already had an opportunity of inspecting the arrangements made by MM. Pierson et Braun with a view to overcoming the difficulties in printing portrait negatives on a large scale. The example set by these gentlemen will be followed without doubt, and the revolution will not be long in spreading to other studios.

ERNEST LACAN.

#### EXPERIENCES OF A PORTRAIT PHOTOGRAPHER.

BY J. R. SAWYER.

IN laying before the readers of the PHOTOGRAPHIC NEWS the following brief notes, I do not imagine that I am telling anything but a "thrice told tale," and that those readers who expect to find novelty in what I am now writing will probably be disappointed; however, as no one contemplates the same subject from absolutely the same point of view, I am tempted, in response to the invitation of the Editor, to jot down a few notes of what I remember in the course of a photographic career of twenty years' duration.

When I began photography in '53, it was not at all such plain sailing as it is at present; it was my lot to pitch in just at the time when Daguerrotype was giving way to collodion positives; but those silvered plates—what a nuisance they were! what wheeling and buffing and polishing they used to take, and how a *black* polish was insisted on, and how awfully difficult to get! Then the cunning contrivances to support these precious plates, first over vapour of iodine, then over ditto of bromine, and how they had to be a straw colour at one stage and a blue colour at another, and some other colour ultimately, but what I quite forget. And then the dreadfully long exposures in the camera, and the development with hot mercury, and the sel d'or, and the fixing, and the washing, and the drying off with distilled water. Yes, we who now-a-days simply slip a piece of glass covered with collodion (all ready for use prepared by chemists who make it their business) into a bath of nitrate of silver, then expose and develop, may think our stars that Scott Archer appeared and gave to the world, without fee or reward, his grand invention of photographic collodion. I just knew Archer, a most modest and unassuming man; he died very shortly after, and in comparative poverty, and thousands have profited by his invention, and millions of hearts throughout the wide world have been gladdened by the vast extension of an art which his invention alone rendered possible. Surely if any man deserves honour and acknowledgment from those he has benefited, it is Scott Archer.

In those days there were some great names who did not think it beneath them to illumine from their stores of scientific lore the subject of photography. There was Hunt, Maxwell Lyte, Spiller and Crooke (in partnership) Dr. Diamond, Becquerel, and other foreign savants, and on taking up and looking at the *Photographic Journal* of those days I am not quite certain that the photographic journals of the present day are more interesting, more scientific, or more useful.

However, such were the times when I first dabbled in photography. Having had a quasi-scientific education, and preparing to start in business with a miscellaneous assortment of optical, philosophical, and surgical appliances, I betook myself to an old city in the eastern counties, the most ramshackle tumble-down old shop and premises you ever saw, I set to work to display my lenses, microscopes, thermometers, and various other "ometers," tooth forceps, dissecting knives, surgical pocket cases, and a variety of bright, awful-looking instruments which seemed to strike awe into the many gazers—such terror, indeed, that few, if any, ever ventured into the shop. Things looked gloomy, and days and weeks passed without anything coming into the exchequer. In this quandary I decided to put a camera and lens together, and see if some practical use could not be made of photography; so I went in for collodion positives, there was a small room at the back of the shop lighted by a skylight, and as in those days skylights were considered absolutely indispensable to the practice of photography, I concluded that I was fortunate in the possession of such a necessary. A little cupboard about three feet square formed my operating room, and this little den was the scene of messes and failures innumerable. The members of my household were almost worried out of their lives by my incessant demands upon them for sittings; my neighbours also were placed under frequent requisition to the same end. This was all very well before the charm of novelty wore off, but when that stage arrived, as it very soon did, my photography was voted a positive nuisance. However, after a heart-breaking time of it, things gradually got better. A platform was erected to elevate the "patient" nearer to the light; a canopy hung, to stop the vertical rays beating down upon the head of the unfortunate sitter; a large white sheet, depending from one side and in a curve to the floor, modified the hard shadows produced by the excessive top light; a background of neatly joined brown paper took the place of the old blanket previously

in use, and by slow degrees sufficiently good results were obtained to permit of the exhibition of a show frame of specimens, and inviting the public not to lose the opportunity of securing their portraits, done (as I then believed) in an artistic manner.

Since that time changes innumerable have taken place. On two occasions I nearly caused the downfall of the rickety concern by constructing improved photographic studios. Once I got into a law suit with a neighbour, because I interfered with his "ancient lights," and only got out of the scrape by paying a heavy sum for costs. Misadventures with gas, fire, and water were of frequent occurrence, until at last an intimation reached me that the Corporation had decided to widen and improve our crooked old street, and for that purpose it would be necessary to take down the tumble-down premises I occupied. Weeks and months of negotiation followed, which were ultimately brought to a conclusion by the City Surveyor, rather rashly, pulling down the buildings immediately adjoining mine, the consequence being to very nearly bring down my old place with a run. Soon after this I obtained the grant of a suitable piece of ground a few yards lower down, and proceeded to build an optical, philosophical, and photographic establishment, in a style which the local newspapers, on its completion, were pleased to say, made it "an ornament to the city."

The studio in this building is about five-and-twenty feet in length, by nearly the same in width. It has one large skylight, sloping down to within about five feet of the floor; in addition, it has one sidelight placed in the wall opposite the skylight, and coming very low down. The studio occupies the whole of the top storey, so that the operating room has to be on the floor below, which contains in addition a dressing-room, studio for colouring, and a room for plate cleaning and varnishing.

(To be continued.)

## Correspondence.

### LIFE-SIZE PORTRAITS, DIRECT AND ENLARGED.

Sir,—Please allow me a few words on Mr. Croughton's paper read before the South London Society, and concluded in your last. In the comparison between large portraits taken direct, and enlarged from small ones, the writer states that a most serious and, as he infers, almost insuperable difficulty in taking (say) eighteen-inch pictures direct is from the extreme exposure required. If such be his experience it cannot have been with the use of the most improved appliances. When in scientific matters reference is made to what can be done, it is of course understood that the operator avails himself of the latest knowledge on the subject. With a studio properly lighted the average exposure with a 7D lens of Dallmeyer for 20-inch plates does not exceed forty seconds for ten months of the year. In Mr. Slingsby's studio, on the 12th of January last year, with a very moderate light, and during an intense frost, I saw some of his finest work done in thirty-five seconds, and fully exposed. At the same time card vignettes with  $\frac{3}{4}$ -inch heads and 2B lens required ten seconds. This was not exceptional working, and is on the same ratio as in my own studio, which is a replica of Mr. Slingsby's. Mr. Robinson works fully as rapidly. I fear Mr. Croughton has seen these things done under adverse circumstances, forgetting or unaware that the introduction of the D lenses, with which almost all the fine, large direct work in the late exhibition were done, and corresponding increase in rapidity by improved building and lighting, have within the last four years revolutionized possibilities in the successful execution of large work. At the same time many of the very finest small photographs in England are done in slow lights; but of course if thirty seconds or more have to be given for card-size, a very long exposure must be given for 20-inch plates; but we must not assume this to be anything else than the fault of the studio. It is certainly not an inherent difficulty in the thing itself. I take exception utterly to the statement that a collodion transparency is best if you wish to print direct from the enlarged plate—either a dry plate or carbon tissue is much better. For small enlargements, to be issued as such without much working on, collodion transfers quite supersede a print from an enlarged negative, yielding a far larger number of intermediate

tones, whilst for the painter's purposes, either in oils or water colours, no better medium can be desired. I very well know that specimens from fine negatives can readily be produced as Mr. Croughton indicates, but for actual professional work I can say, as one who has done as many enlargements as most people, that I never expect to see anything so produced to equal the work now being daily produced by leading photographers with suitable large lenses and properly arranged light and chemicals. With regard to the light, I can only say that no man having worked with a quick light straightway desireth a slow, for, he saith, the quick is better.—Very respectfully.  
SAMUEL FRY.

### THE CRAWSHAY COMPETITION.

Sir,—I see it announced that the direct heads in next year's competition are to be in pictures twenty by sixteen and fifteen by twelve. I would be obliged if you can state whether or not the above is the measurement allowed for the print, and what margin is to be allowed for the mount and frame.—I am, &c.,

29th December, 1873.

INTENDING COMPETITOR.

[The dimensions mentioned refer to the picture so far as that legitimately comprises head, bust, and requisite background. In short, it is intended that the portrait shall be taken fairly on a plate not less than the size indicated, twenty by sixteen, or fifteen by twelve. The margin, mounting, &c., are left to the taste of the competitor. Some, for instance, at the last competition had white mounts and gold frame; some gold mounts and black frame; some had a surrounding margin of purple brown photographically printed; but the pictures were of the proper size within that tinted margin.]

EDITOR.

### YELLOW SPOTS.

Sir,—Seeing many of your correspondents writing about those troublesome minute yellow spots, permit me to say, having been similarly afflicted with my prints for some time, and having tried several remedies, but all proved failures, until a friend of mine (who is a chemist) lately told me that the cause of the spots was washing the prints in cold water after being removed from the fixer, which being made with warm water to keep the hypo soluble, and being thus suddenly changed from the warm fixing bath to cold water (which is exceedingly cold at this time of the year), closes up the pores of the paper, and thus keep the hypo, as it were, frozen up in the paper.

I have tried washing the prints after fixing in warm water, and find it a success. The theory of it seems to me to be the warm water readily dissolves the free hypo from the paper, whilst cold water fixes it in the paper. This seems to be, the more feasible, as the spots are more prevalent in winter than in summer, when the water is warmer.—Yours truly,

Truro, 17th December, 1873.

FREDK. ARGALL.

## Proceedings of Societies.

### MANCHESTER PHOTOGRAPHIC SOCIETY.

The usual monthly meeting was held at the Memorial Hall, on Thursday evening, the 11th Dec., Mr. W. T. MABLEY, President, in the chair.

The routine business was disposed of, and Mr. I. W. Petty elected a member of the Society.

Mr. A. Brothers exhibited a series of photo-lithographs from Burgman's "Triumphs of Maximilian I." He said that the original wood engravings were on separate sheets of large folio size, and represented a procession; but the photo-lithographs were joined and suspended against the wall of the meeting-room, suggesting the effect of a frieze. The designs are very spirited, and are considered to be the very finest examples of the art of wood-engraving at its best period—the sixteenth century. The series comprised sixty-eight sheets—one half of the work. The reproductions have been made for the Holbein Society.

Mr. Brothers then read a short paper "On the Sciopticon for Enlarging" (see page 4), and exhibited the only two prints he had produced. They were both very satisfactory specimens.

Mr. Brier exhibited two transparencies, and an autotype composition picture, with sheep. He showed also several silver and autotype prints of the same subjects for comparison.

Mr. Heywood exhibited a picture by Mr. R. Mitchell—a street scene, with figures. He understood from Mr. Mitchell that the negative was taken on one of Mr. Mitchell's dry plates (secret process) in ninety seconds.

Mr. M. NOTON read a paper "On the Manufacture of Limes for the Lantern" (see page 3), and produced a light for illustration. The light was good, and seemed to have more blue rays in it than are obtained from the ordinary limes.

Mr. WOODWARD said, and gum would have the effect of breaking up these limes in consequence of the liberation of carbonic acid gas. He had found it a good plan to powder the necessary quantity of gum, and to mix it with the other ingredients before adding the water.

The siphon was used by the members for trying a number of slides, and retained its previous popularity.

The usual complimentary votes were passed, and the meeting, which was unusually well attended, was then adjourned.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE second popular meeting of the season was held in Queen Street Hall, on Wednesday evening, the 17th Dec., with an audience which filled the hall in every part.

The Exhibition consisted of a series of pictures illustrative of tours in North Wales, and was accompanied by a descriptive lecture by Dr. John Nicol.

The attention of the audience was maintained for an hour and a quarter, and the pictures elicited frequent bursts of applause. At the close of the Exhibition Dr. Nicol said that although the council would doubtless thank Mr. Alfred Pumphrey, of Birmingham, to whose kindness they were indebted for the very successful exhibition, he thought it right to give the audience an opportunity of expressing their appreciation also. He therefore proposed that a vote of thanks be given to that gentleman for his liberality on this as well as on former occasions. The motion was enthusiastically responded to.

### Talk in the Studio.

**PRESERVING SOLUTIONS OF GUM-ARABIC.**—The following is said by M. Hirschberg to prevent this gum from moulding:—A little concentrated sulphuric acid is added, which precipitates the lime present. Solutions treated in this manner have been kept for eighteen months without losing their adhesiveness or growing mouldy.

**AUSTRIAN COMPLIMENT TO ENGLISH PHOTOGRAPHY.**—The Photographic Society at Vienna, in selecting a presentation to its members for this year, have chosen four of the photographs exhibited by Messrs. Robinson and Cherrill at the Vienna International Exhibition. These will be reproduced and printed for distribution by Herr Albert's photo-collographic process. Messrs. Robinson and Cherrill have presented the originals to the Vienna Society.

**DISAFFECTION IN THE PHOTOGRAPHIC SOCIETY.**—A correspondent states that a requisition, signed by twenty members, has been forwarded to the council of the Photographic Society of London, asking the appointment of a special meeting to reconsider and modify some of the rules. Our correspondent states that the ostensible reason for change is to secure a larger infusion of new blood into the council, a more active interest amongst the members in the society's affairs, and an annual change in the presidency. He also alleges that "the real reasons of the disaffection which originates with a very few persons, are, in one or two, bitter disappointment and grudge in relation to the late award of medals; in one or two more disappointment at not being proposed in the council nominations for the coming year; and in one or two more personal pique." A veritable Cave of Adullam, if our correspondent be correct! As the question will doubtless shortly come before the public in a regular form, it is scarcely worth while to consider speculative points at present.

### To Correspondents.

E. R. D. —We do not know the address of a masker. As a rule, they prefer to work for the trade rather than for individuals, and hence offer no facility to private customers. Your best plan will be to get information from the dealer who supplies your goods, and then select. He also will doubtless get your plate re-burnished.

W. A. N. —We are not familiar with the special printing press to which you refer, but we believe that any good platen press, such as is used for ordinary letter-press printing, will answer for photo-collographic printing. 2. So far as we know you may use any of the processes we have published in the NEWS, during the last few years, in New South Wales. Albert's process, of which we have given repeated details, produces capital results.

**COLLO.**—The size of the mount of the cabinet portrait is six and-a-half inches by four and a-quarter inches. The prints are generally about five and a-half by four inches; but vary slightly according to the taste of the photographer. The "Victoria" is not a recognized size in this country, nor, so far as we are aware, is it generally adopted anywhere. It is a term which has been applied to a size between the card and cabinet, which has never acquired general acceptance. 2. The only method of testing the strength of a printing bath is by precipitating the whole of the silver in a measured portion of solution, and weighing it. You will find the method described in our YEAR-BOOK for 1870, page 115, and in various volumes of the NEWS. Mr. Hart's Volumetric Apparatus is an excellent aid to the process. The argentometer is useless in testing a printing bath. 3. The lens in question may be used for cabinet, where vignette heads or medallion heads are required; but would require a small stop if used for full-length figures.

B. P.—The brown markings in your print are due to a fault in the paper. The albumen has run in an uneven wave, and where the albumen is in excess the print is of a browner or redder tint.

J. C. BRADSHAW.—The phenomenon is a very familiar one. Almost every one has noticed that on looking at a window for a short time, and then removing the eyes, a reversed image of it remains for a few moments. It is analogous to the perception of complementary colours under similar circumstances.

F. N. T.—The term "photo-mezzotints" was employed by Carl Meinerth to describe the prints obtained by printing through a medium; that is, the paper not in contact with the negative. A thin plate of glass being interposed, and direct sunlight printing employed, gives a soft image without perfect sharpness.

G. L.—We have heard some of the details you state; but it is scarcely worth while to publish them. The matter is scarcely important enough to dignify with the title of "conspiracy."

A. B.—Your transfer enclosed is under-exposed and over-developed; in short, it is fogged; the image being buried in a general veil. The streaks are due to the wax, of which too much has been left on the plate. It should be rubbed until no perceptible trace remains, the glass having been carefully cleaned first. Toning is not always necessary, but is sometimes valuable, not only in improving the colour, but in clearing the image of the smoky smudged effect which occurs under some conditions. Use a somewhat weaker solution, and if the chloride of gold be very acid, as yours appears to have been, neutralize it. If you wish to transfer the film when wet, you must learn to manipulate with sufficient skill in lifting the film. When it is loose on the plate, place the transfer paper upon it, and press down with a squeegee. Or allow the film to float in a dish of water, place the transfer paper underneath, and with a camel's hair pencil move the film into position, and lift both out together. Patience and the gradual acquisition of experience will accomplish much. You will find an article on the subject in our YEAR-BOOK, and shortly some further detailed articles on the subject will appear in the NEWS.

**NOTICE.**—Copying from a glass positive is not an easy operation, and rarely gives very successful results. It is difficult for us to form an idea how far you have been successful in the examples forwarded, inasmuch as we cannot tell to what extent the defects in your prints are due to defects in the original. No. 1 is insufficiently toned; No. 2 is imperfectly fixed, the mottled brown effect being due to imperfect fixation; No. 3 is the best, and may possibly be a moderately good copy of an imperfect original.

H. W.—We cannot tell you with certainty which form of ounce any special formula is intended to express—thanks to the confused muddle in which English weights and measures remain; but, as a rule, it is understood that in photographic formulae the ounce of 480 grains is understood. 2. In the case described, where a plate has been over-exposed, the image rapidly flashes out on applying the alkaline developer, and if it be not washed at once as described, the image almost as rapidly disappears, a general reduction covering the surface of the plate. The appearance is very similar, in fact, to that of an ordinary wet plate under similar circumstances. When development is going on properly the image gradually acquires more force; but when fogging sets in the image begins to disappear, because the whole surface is becoming reduced instead of the image only.

**SPOTS ON NEGATIVE.**—Wash the gum thoroughly off the surface, and then apply strong fresh hypo or weak cyanide, which will at once remove the spots.

D. D. (Belgian Subscriber).—Many thanks. Your communication arrived too late, unfortunately, for the YEAR-BOOK, but shall appear in the NEWS.

E. GARLICK.—Thanks. Your useful hint shall appear in our next.

M. C.—Thanks. Your communication did not reach us in time for the YEAR-BOOK.

N. G.—Your negatives were received a few days ago without any letter. Letter received just as we go to press. Answer in our next.

C. A. FERNUEY.—Your carbon print is very good as a beginning. Thanks and reciprocations.

Several Correspondents in our next.

## The Photographic News, January 9, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. SCIENTIFIC SOCIETIES' CLUB—PHOTOGRAPHY NOT ALWAYS DESIRABLE—THE PROGRESS OF LICHTDRUCK—MERCANTILE PHOTOGRAPHY.

*Scientific Societies' Club.*—There is a proposal to form a club in connection with scientific societies, at which members of the various societies in London can meet together, and enjoy social intercourse. So many of the members reside out of town that it is felt that a club of the nature contemplated could not fail to be popular. Already a very strong provisional committee has been formed, which includes among its number several members of the chemical and photographic societies, and there seems no doubt that the club will be founded at an early day. It is proposed to have a site in the vicinity of Burlington House, the entrance fee and subscription being very moderate for a West-end Club. The annual subscription proposed will be but three guineas for town members, and a guinea and a half for country members; while those who are original members will pay rather less. Such a club, it is suggested, will be of especial value to men resident in the provinces, who would find it a convenient rendezvous when in town, and it is proposed to make the institution useful in the highest sense to scientific men by having, in addition to ordinary club requisites, books of reference and scientific apparatus for the use of the members. The honorary secretary *pro. tem.* is J. Logan Lobley, Esq., F.G.S., 59, Clarendon Road, W., and among the present committee may be cited the names of Dr. Hall Gladstone, F.R.S., E. W. Cook, F.R.S., H. Woodward, F.R.S., Dr. Wallick, Prof. Church, Lord de Blaquière, Rev. C. Pritchard, F.R.S., Dr. Dupré, &c., the list affording a good guarantee that the club will be well supported.

*Photography not always desirable.*—There are some circumstances under which the aid of photography is best not invoked, and an incident we are about to allude to is certainly one of them. A friend, who is much given to yachting and boating, has often invited us to his place, near Gravesend, to join in a water excursion, or to make one of the crew during a sailing match. The intended visit has never come off, although renewed year after year, accompanied by sailor-like descriptions as to how well the yacht behaved under the hands of its owner; how bravely she had weathered the most terrific gales; and how jolly it was on board of a night, sleeping in the snug little cabin. The yacht was, in fact, our friend's hobby, and he was never tired of talking of her. She had never been second in a race with craft of the same burden, the weather was never too dirty for her to venture abroad, and her beauty under full sail, we were assured, could only be fitly described in a poem. To tell the truth, we were in our turn rather proud of our friend, and he used to do duty very often in conversation, being referred to as "an intimate friend who is a yacht owner," or "a man who sails one of the best racing craft on the coast, and who is always sending invitations for a cruise." But one unfortunate day our shipowner had his vessel photographed, and, although he did not favour us with a copy of the picture, we had an opportunity of seeing it a little while afterwards. Perhaps photography had not done the craft justice—the art is often inveighed against—but, in any case, the result had a most disheartening effect. Romantic notions that had been formed by the florid descriptions given vanished into thin air; for, instead of a schooner-rigged yacht of some fifty tons or so, with milk white decks and shining brass fittings, there was nothing apparently but an ugly iron boat, fitted with a mast, with a clumsy coffin-like box on board that served as cabin. How much better it would have been to have had a charming little fancy sketch in water colour, showing the swift little yacht with snow white sails, scudding along at some dis-

tance from shore over the bright blue billows, with every stitch of canvass set, and the gallant owner half way up the rigging!

*The Progress of Lichtdruck.*—One often sees little albums or strings of miniature views got up for sale to visitors at fashionable watering-places or frequented districts. Some years ago it was the fashion to print such pictures of a vivid salmon colour, with foliage, mountains, and bricks and mortar all of the same flesh-like hue; but more recently they have been produced of a greyish tone upon a highly glazed surface, to resemble photographs, for which they are very often taken. Indeed, we have seen visitors, when purchasing pictures to carry home with them as *souvenirs*, turn over a mixed collection of real photographs and these spurious imitations, and select out the latter, because in these the snow mountains were depicted much more white and prominent, the steamboats on the lakes more vividly, and the architecture more imposing. In the photograph the grandeur of nature was quite tame in comparison, for Mont Blanc—say, taken from Geneva—appears so low and insignificant, that, however much it may be in accord with reality, it does not come up to a traveller's notions, and will, as he knows very well, be disappointing to his friends at home, and so the more striking prints are selected. Of course, the camera pictures, taken at close quarters on the glaciers, showing deep crevasses and huge cornices of snow and ice, such as Mr. England has given us, are grand enough in all conscience, but the greater portion of the travelling public in Switzerland do not venture so near the scenes, but confine themselves to looking at them from a distance in their excursions from Geneva, Chamounix, Lucerne, Zermatt, &c. It is for this reason that the spurious pictures, being a little more exaggerated than the real photographs, are accepted by the general public, who, however, imagine at the time they are really purchasing pictures taken in the camera. Some of these lithographs are exceedingly well done, being most accurately copied from photographs, only the spires and mountains are made a little more lofty, and lakes and waterfalls a little more extensive. But now these sham productions seem on the eve of disappearing, for with the producer the great question is simply that of cost, and if the real thing can be provided for the same money as the spurious one, he has, of course, no objection against selling the genuine article, and, so long as he can get as many of them, turning an honest penny. A collection of prints that recently came under our attention, consisting of views on the Rhine, in tiny albums, proved on careful inspection—for a sound examination was very necessary—to be in part real photographs. They were, in fact, Lichtdrucks, but printed on grey paper on a white mount, and glazed all over just like the common lithographs, of which another album consisted. In fact, a casual observer, or even one on his guard against spurious photographs, would at once reject them as being unmistakably of the latter kind, for such care had been taken to make the genuine thing look like a counterfeit, and the effect was so successful, that at first sight an experienced eye would have been mistaken. It is to be hoped that the time will soon come when such photographs will be put forward for what they really are, for as soon as the public learn that the pictures are not only real photographs, but also of a permanent nature, a ready sale of them may be relied upon. The cost of the little album to which we refer, and which contained nearly a score of Lichtdrucks, was about one-and-sixpence.

*Mercantile Photography.*—Merchants and shippers are fully alive to the use of photography. All new pictures of hardware and cutlery are photographed, and dispersed to retail houses or carried round by travellers, and the sale is often effected simply through the medium of the photographed samples. In shipping goods to the Colonies, the little pictures serve their purpose even better. At the same time that a cargo is being shipped in this country to Australia, or other like country, a set of photographs is

dispatched by mail, showing the nature of the goods forwarded, and by the time the ship arrives every bit of its cargo has already been sold by the aid of the photographs. There is no delay in unpacking, and sampling, and hawking round of patterns before the sale of the cargo is effected, but the goods are bought and paid for the moment the vessel arrives in port, the merchants sometimes obtaining their money two or three months sooner than was the case formerly. Here, therefore, is photography serving mercantile interests in a most essential manner, and taking the place, in a great measure, of the commercial traveller. The art can be trusted with less hesitation than many good gentlemen of this talkative fraternity, and it inspires more confidence than all the fine drawings and sketches in the world. Buyers would demur purchasing goods from a long way off on the strength of a draughtsman's sketch, just in the same way as a thrifty housewife would decline to furnish her house through the medium of an illustrated catalogue; but it is different when one sees a photograph produced accurately to scale. In most cases it would serve all the purposes of the pattern sample itself.

### A MONTH'S TRIP WITH MY CAMERA.

BY REUBEN MITCHELL.\*

RETURNING to our hotel, the following morning proving fine, we started after breakfast with our camera to take views of our favourite subjects, and fixed on a very suitable position much nearer to the town than the cemetery. There was considerable haze in the distance, and we waited some time, but it did not entirely clear away. We exposed several plates, and secured some fine pictures. Returning into the town, we exposed others from the bridge across the river Seine, and these completed our camera operations; and we developed both our Paris and Rouen subjects on our return home to England. During the afternoon we again visited several of the fine churches, and took a last look at these splendid structures. We returned to the hotel, and packed our things ready for leaving Rouen on the following morning. After breakfast our baggage was stowed away on an omnibus; my friend settled our accounts; we bid our kind friends adieu, and drove to the railway station on our way to Boulogne home again—a most pleasant sensation, if rambling about only for a few weeks. We were soon seated, and off we went, passing through an uninteresting country. Arriving at Amiens we had to change, and wait for the train for Boulogne. There is a very fine buffet at Amiens, and well conducted; the viands excellent, and ready on the arrival of the train. We had outlets with grated potatoes, and good soup and claret; very civil and attentive waiters. Many of our English eaters at the refreshment rooms at our railway stations would do well to make a tour in France, and see the difference in the comfort in theirs and the discomfort of ours; also the difference in the quality of the viands. The train for Boulogne rolled into the station, and our baggage and ourselves were quickly in the train. Leaving Amiens, we passed some of the fortifications that had been made during the late war. The town appeared to be a thriving place, as there were numbers of new buildings; also some weaving sheds, and other works. The country is very flat from here to Boulogne, and in many places there are large tracts of swamp, the river flowing deep and sluggish. There are large numbers of fine tall poplar trees along the banks of the river, with numerous rustic farmsteads, and small villages or hamlets along the line of rail, nestling among trees and shrubs. There are also large market gardens, with melons growing in abundance in the open air, and numerous fields of fine flax. The land here seems to favour its growth. After leaving Abbeville the railway runs along the coast to Boulogne, frequently giving us

glimpses of the sea; also many very fine subjects both for the camera and the painter. Arriving at Boulogne, we were much disappointed at having to wait till after midnight before we could cross the Channel to Folkstone, and as there was no other alternative we had our luggage conveyed to a hotel on the quay, within a short distance of where the steamer was moored that we intended crossing the Channel in. We took a stroll, but Boulogne is not a very interesting place, except for its notoriety as a fashionable watering place. There is a very large hotel overlooking the sea. The sands and shore are very fine, and well suited for bathing. There is a small pleasure garden near the large hotel, and an excellent band was playing for the amusement of the visitors, who appeared to be principally English. We dined at the table d'hôte, and had another stroll, but nothing attractive came in our way. At 12.30 p.m. we ordered our luggage on board the steamer, and when we entered the cabin all the berths were engaged, only one of the large form-like berths being at liberty. My friend decided to go on deck, and I laid down as soon as we were out in the Channel. The steamer rolled and pitched about, and it was with some difficulty I could keep from being tossed on the cabin floor. We arrived at Folkstone long before daylight, and coming on deck we made our way to the Custom House, where we had to wait some time before our luggage was brought in for examination. We had little difficulty in getting it passed and transferred to the railway station close at hand. One of the officials kindly directed us to a small hotel that was open for the reception of passengers arriving by the steamers. On entering we found many of those who had come by the same steamer as ourselves, and we all looked rather seedy; but a little refreshment, consisting of a cup of warm tea, was very acceptable. We had to wait some time for the train; but on moving once more in old England there is a sensation of pleasure which can only be appreciated by those who have left their native soil, if only for one short month. The route from Folkstone to London, by way of Tunbridge Wells, is very interesting. We at last rolled into Charing Cross Station about eleven o'clock a.m., and stopped in London all night, but having a number of plates undeveloped, I was very anxious about them, so I left on the following day by the eleven o'clock train. My excellent friend, having business to transact, remained in London, so we had to part company, after one of the pleasantest and most enjoyable trips imaginable, and arrived safely in Bolton.

I have penned these notes from memory since my return home, simply describing what we saw and came in contact with, hoping they may be of some service to future travellers in the country we passed through.

### AMERICAN CORRESPONDENCE.\*

*An Error and its Remedy.*—As you are famous for making large work in England, not to say "monstrosities," the following ingenious method (for which I am indebted to Mr. O. G. Mason, photographer at the Bellevue Hospital) of "backing out" of a mistake after you have made it, may be of use to some of your readers. Mr. Mason writes me as follows:—

"A few months since I received a note, requesting me to call at the office of a prominent railroad company 'upon professional business.' On answering the request, I was ushered into a long hall, upon one side of which hung a map forty feet long and nine feet wide, highly finished in water colour, such as was deemed best for representing the conformation, variety, and general geographical features of the vast tract of our territory lying between Lake Superior and Puget Sound, on the Pacific Ocean. The timber land was represented by seemingly numberless miniature trees in deep green; the mountains in blue, white, and brown; rivers, lakes, and ocean, in brilliant blue, &c. This map I was asked to photograph to quarter scale, which would make my copy about ten feet by twenty-five inches, exclusive of margin. With

\* Concluded from page 3.

\* Continued from page 2.

due degree of hesitation, I undertook the work, before learning, as I afterwards did, that it had been pronounced impossible by others who had examined it. Of course it would not be feasible to use a plate ten feet long, and the width of the hall would not admit of working a proper lens for producing an image in sections twenty-five inches high. I was therefore obliged to remove the map to other quarters, and as my own place was fully occupied by special work which I could not well defer, I made arrangements for the use of the operating room of a skilful friend, whose reputation led me to engage his assistance on the work. The map was carefully rolled and, with the aid of four men, removed to the place selected. I concluded to make the copy in six sections, upon 30 × 26 inch plates. A plank frame as high as the map was wide, and one-fourth its length, was erected upon a movable platform, and securely fastened in a true perpendicular. About ten feet of the map was then unrolled and held to the frame by tacks driven through the heavy silk binding which covered the outer edge of the margin. The camera was placed in position, focus arranged, and a trial plate made; everything appeared satisfactory.

"This preparatory work had consumed most of the first day; and in order to insure our labour for readiness to begin early the next morning, we nailed both the camera-stand and the platform on which the map was mounted, to the floor. The great value of the map was such, that, for safety against accident, by storm or otherwise, it was taken down, re-rolled, and placed in its metallic case. When I reached the operating room on the next morning, I found my friend and his assistants busily making a negative of the first section of the map, which they had again placed in position. Upon inquiry I was told that careful measurements of the image on the focussing screen had been made, and everything found satisfactory as on the day previous. The work was proceeded with, the whole day being required for its completion, although we had no failures from error in timing a single exposure or in manipulation. But the heft of the map, and the great care required in handling it, made the work necessarily slow.

"On the next morning the negatives were varnished, and the printing began. Some idea may be formed of my surprise when, on the fourth morning from the beginning of the work, I attempted to mount an entire copy of the great map, and found that the sheets would not join, or rather, that the border and all geographical lines failed to meet. Upon measuring the negatives, I found that the left-hand end of each image was one-fourth of an inch larger than the right-hand ends on the same plate. Owing to some error in measurement, or change of position after exposure of the trial plate, the whole series had been made without the original having been at a true right-angle with the axis of the lens; hence the distortion. What could be done to remedy the defect? Making a new set of negatives was out of the question, as the original was then far on its way across the Atlantic Ocean. The order was an important one; large sums of money were expected by the company, and some by myself, if the work could be successfully completed. After some days' experimenting, I constructed a mounting table, large enough for the whole copy when mounted, around which was fitted a stretcher frame, which could be easily removed at will. Upon this frame I tightly stretched thin muslin, known in the trade as 'strainer muslin.' The narrow side of each sheet was spread with thin starch paste, the proper consistency having been determined by experiment, gradually working it over the entire sheet, which was then quickly laid on the stretched muslin, and the narrow end expanded by a gentle pulling pressure of the hands, until certain lines on the print should coincide with others previously drawn parallel by the use of a long straightedge, the entire length of ten feet. The stretcher was then removed from the table and allowed to hang by one edge, sustained along the central portions by slats or braces to prevent the sides from springing inward by contraction of the drying prints. When thoroughly dry, the entire map was stripped from the thin muslin, a process rendered easy by the porous nature of the material and the thin starch used in mounting.

"The prints were then remounted with strong 'bookbinders' paste on firm heavy muslin, upon which parallel lines had been ruled as in the former case, to serve as a guide for any further expansion, which was usually found necessary in places, in order that all the lines might meet properly.

"In this way the error in making the negatives was by a large amount of work corrected, and the photographic copies of the great map delivered with satisfaction to all except the maker, whose profit on the estimated price had, by the extra work

required, been reduced, until it had changed to the wrong side of the balance sheet.

*Retouching at Night.*—A great many photographers whose circumstances compel them to do with little assistance will find the following of use to them. It is sent me by Herr. F. Weadling, of Vienna:—

"Doubtless many photographers have tried to use artificial light for retouching the negative, but, it seems, without result. I never read or heard of success. I have made also different efforts in that way; but in the last winter before Christmas-time work pressed me to make another experiment. I tried a petroleum lamp, with round burner, and fastened to it—in order to secure a stronger light and parallel beams—the parabolic mirror of my magnesium lamp. I gained an intensive light, to be sure; but on retouching, I felt my eyes very much affected, not being able to work long.

"Now, I remembered that once a watchmaker told me he was able to work easily in the evening, since he employed the light blue glass (called optical glass); and I followed him in using that material. The effect was excellent, and since I have retouched a great number of negatives in the winter past at night.

"As the parabolic (or spherical) mirror concentrates also the heat beams, it would perhaps be an improvement to use instead of the blue glass a 'cuvette,' containing a solution of sulphate of copper with ammonia or Prussian blue dissolved in oxalic acid.

"I think if you publish this, that the apparatus will in a short time be in every photographer's hands, because it is a welcome requisite, although it may be considered both tough and very simple—a very egg of Columbus."

Wishing you all a clearance of the fog, and a happy new year.—Truly yours,

EDWARD L. WILSON.

Philadelphia, Dec. 15th, 1873.

#### NOTES ON PHOTOGRAPHY IN THE ARCTIC REGIONS.

BY LIEUT. CHERMSIDE, R.E.\*

MR. PRESIDENT and Members of the Photographic Society: I have at the same time to express to you my thanks for the honour you have done me in asking me to read a paper on "Photography in the Arctic Regions" before you, and my regret that such opportunities as I enjoyed of studying the effects of the light, temperature, and the rarefaction of the atmosphere on the ordinary photographic processes, should have fallen to the lot of such a novice in the art as myself, and therefore to one little likely to derive therefrom much information of practical value.

As, however, so little has hitherto been done in the way of Arctic photography, I trust that photographers may be able to, at any rate, deduce some conclusions of interest from my experiences. The only existing Arctic photographs that I know of, besides Mr. Leigh Smith's, have been taken by Americans, Austrians, and Swedes. Those taken by the Americans are most interesting, and form a large series illustrating an expedition to Baffin's Bay in 1869, undertaken by the artist William Bradford solely for art purposes. Mr. Bradford was accompanied by two professional photographers of Boston, U.S., and their complete and valuable series has recently been published. Of the Austrian photographs I know nothing, but conclude they were taken in Lieut. Weyprecht's expedition of 1871. Those forming the Swedish collection were taken in 1872-3, and are on plates about 6in. by 8in. I have seen the negatives, and shortly expect some prints.

All the photographs that I have seen are marked more or less by the same characteristic defects, a want of density, and dark mottled stains, as if produced by an uneven mixture of the constituents of the developing solution, to which I shall have occasion to allude again. As regards our own collection, I should like to say, before describing our photographic difficulties, labours, and results, that photography was with us merely an experiment, and, anxious as we were for its success, it was always of secondary importance to our main object, exploration to the north. We therefore only found ourselves in bays and fiords when driven in by gales

\* Read before the Photographic Society of London.

or ice, or for surveying and shooting purposes, and the opportunities of photographing the striking features had then to be seized without much reference to the artistic considerations of the best light and time of day for taking each particular subject, or the best position from which to take it.

Owing to my being detained in Ireland until within a few days of starting, four or five days' practical instruction was unfortunately my total stock of experience.

Mr. Leigh Smith, whose guest I was to be, left all arrangements as regarded photography in my hands. He had already a small travelling camera, and apparatus for dry plates 7in. by 9in.; and Mr. Thomas, at a very short notice, supplied us with a complete apparatus for wet-plate photography, with plates 10in. by 8in., with the exception of a tent, as we expected to knock up an operating-room on board. Only arriving at Dundee twenty-four hours before the ship sailed, I had no time for further preparations, and on the 10th of May we sailed for the north.

It was not till the beginning of June, on finding the north-eastern trend of the ice along which we were cruising in search of an opening leading us towards Spitzbergen, that we began to think of photography. It was a matter of some time and thought to unpack and stow in a small ship's cabin, already crowded with the instruments and apparatus pertaining to other pursuits, the fragile paraphernalia of a photographic apparatus, especially as we were experiencing very rough weather; it was, however, successfully done, and I may add that during the whole voyage we never had a smash, except from such accidents as might happen on shore.

I may here describe our operating room; it was a mere cupboard, in which you could barely stand upright, four to five feet long, and a little over three feet in width, lighted in one corner by the small round port protected outside by iron bars, as is necessary in all ships intended for ice-work, so that the quantity of light was a minimum; and many of the defects noticeable in our negatives are, I think, due to our having to develop them in almost total darkness. A candle, when placed at a convenient height, either burnt the ceiling, or, from the proximity of the tin guard above it, caused a lot of smoke apparently deleterious to the photographs; it was, moreover, unavoidably in the way, and, owing to the impracticability of getting its light in the right place, its use was abandoned. A movable wooden frame was fixed in front of the port whenever the room was required for photographic purposes, and this was covered with only a single thickness of yellow tannin, as with two thicknesses, or even a single one, of orange-coloured paper, one could see nothing. We also experienced much difficulty in the way of manipulation from the want of a sink, tap, and cistern; and a basin and small jug, which had to be placed on the floor and lifted when required, decidedly increased the difficulties of handling plates 10 by 8 inches, and of the prompt application of water so often necessary. We suffered a good deal from the condensation of moisture, which took place readily in so confined a space; and which gave rise to streakiness and other defects in the plates. A deck-house, if it could be warmed, would undoubtedly be a good arrangement; but from the difficulty of warming it, I do not think a tent will prove of much use.

On the 8th of June we reached King's Bay, Spitzbergen, lat. 79° N., long. 12° E.; and the jagged peaks of the mountains, with here and there dark patches of hard slate or quartzite showing through their snowy covering, the immense glaciers, like frozen rivers, winding down the gullies and ravines between them, all lying bathed in the sunlight of an Arctic summer night, promised a fair field for the camera. The next day was spent in futile attempts at photography; and perhaps an account of them may be the best way of illustrating the difficulties we encountered.

The camera is first taken ashore about a quarter of a mile, the passage being at some times of tides rather obstructed by ice, and we at once meet the difficulty that the Arctic photographer continually encounters—namely, that of locomotion. The ground is ragged and rocky, covered with snow from one to three or four feet deep, all very slushy from the

fierce heat of the June sun, and serving to carefully conceal the holes between the stones, so that the greatest difficulty is continually occurring in selecting a suitable position. However, the position is at last selected, and a firm hold for the legs of the stand obtained below the snow, the view focussed, and the stop decided upon. Returning to the ship we clean, coat, and sensitise a plate; another journey to and fro, and after exposure the plate is handed up the ship's side, and the operator retires into his den. Having attached the plate-holder I pour on the developer (iron 30 grs.), and soon a horrid thought seizes me that every detail required for the production of a negative has been carefully carried out, with the trifling exception of opening the slide. Five minutes' application of the developer persuades me that such must have been the case, as I fail to perceive any symptoms of the film having seen the light. Sorrowfully another plate is prepared, and the laborious journey by water, ice, and snow again performed with a like result. After trying it a third time we bring the camera on board, and take to merely exposing plates for experiment. Up to this time we had given to each of our attempts 8, 10, and 15 seconds' exposure. There is a good deal of motion on board, but exposure to the light should be plainly indicated. By the use of heated developer and a 40-second exposure we succeed in obtaining the faintest of images, but no more; and, disgusted, we give it up, and go in for dry plates. These prove an equal failure, owing chiefly, however, I imagine, to the age of the plates, which was two years, as this lot we subsequently from time to time came across bad batches. So we put away our apparatus in anything but a contented frame of mind, and go out shooting.

The temperatures of the air this day were:—4 A.M. 28° F.; 10 A.M., 36° F.; 12 noon, 34° F.; 9 P.M., 33° F.; 1 A.M. 31° F.  
(To be continued.)

## EXPERIENCES OF A PORTRAIT PHOTOGRAPHER

BY J. R. SAWYER.\*

DURING the course of my twenty years' experience I have seen many things which have touched me deeply—many things to move both to laughter and to tears. A photographer sees many sides of human character. He sees its vanity, its pettiness and ill-humour; he also sees its devotion, its love, and its kindness. Children who were my sitters have grown up to young men and women, and have brought in their turn their own little ones to the same artist to whom they themselves sat. Old people have dropped off, and left behind them loving ones, whom photography has blessed by allowing them to preserve mementos of the departed.

I suppose that every practitioner has his share of queer jobs. One of the most difficult I ever had was in the beginning of the Volunteer movement, and I was requested to make arrangements for photographing our contingent in the national defence at a grand review, which was to take place in Lord L——'s park, at 11—. It was necessary that the plate should be of a fairly large size, so I decided upon twelve by ten, and with my traps and impedimenta found myself, early on the day in question, at the little station near the review ground, with some hundreds of volunteers. What a confusion there was, to be sure. Here a general, bewailing the loss of his cocked hat; there a bandmaster who had lost sight of his musicians; here a captain without a company; and there a company without any officers whatever. However, matters got righted somehow, and we were soon *en route* for the battle field (otherwise review ground). What a splendid day it was! Bright summer time, soft breeze, turf like velvet, fine old trees spreading their luxurious branches, covered with the richest verdure, a magnificent mansion, ornamental grounds, and thousands of spectators, who had congregated from all parts of the county, made it altogether as pretty a sight as one could wish to see. But now came my special difficulties. I had chartered a waggon, partly because it would

\* Continued from page 11.

give me an elevation upon which to poise my camera-stand, and partly because there would be room enough in it to erect my tent. But how to get this precious waggon on to the review ground was another matter. Wherever I presented myself I seemed doomed to be turned back. At last I was fortunate enough to obtain, by dint of a good deal of hard work, a written permission from the reviewing officer to pass the line of sentries; but here my troubles did not end. My driver whips up his horses, and we achieve an advantageous position. Down came an aide-de-camp, like a thunderbolt, with a gruff demand to know what we were doing there. Explanations not being satisfactory, we had to move off. The same sort of thing occurred again and again, until at last I became sick and tired, and began to think seriously of packing up and taking myself off. However, after my last tormentor had left, a notion seized me, upon which I immediately acted. I directed the driver to place the waggon in a first-rate position just under a big tree, to take out his horses, take himself off, and return in some four hours or so. As soon as my vehicle was perceived in its new position down came my friend again, and insisted upon my moving. I showed my permission, explained the circumstances of the case; that I was engaged to do certain work; that that was the only point of view from which to do it, and inasmuch as I had neither horses nor driver I *could* not move, if it was ever so much desired. This last was a poser. Just then the bugles rang out the "assembly." My friends were feign to leave matters as they stood, and so I remained unmolested. The troops fell in; the lord lieutenant of the county, surrounded by a brilliant staff, galloped into the open; the words "Present arms!" ran along the line; the band struck up "God save the Queen." At that moment I uncapped the lens, and got a negative sufficiently satisfactory to have some hundreds of copies printed from it.

In my own experience I have generally found the conduct of a photographic business a comparatively simple affair. I have never troubled myself much about the state of my bath; for instance, I was profoundly indifferent as to its acidity or alkalinity provided it took good pictures, and something like the following is the plan I have generally adopted. In making up a fresh bath, I simply dissolved commercial nitrate of silver in distilled or clean rain water, and then added to it a small quantity of a strong solution of carbonate of soda; this I filtered, then putting a small quantity into a flat well bath, coated a plate thickly with collodion, and left it in all night; I have generally found it in perfect working order next day. When this small quantity begins to show signs of deterioration, I filter it back into the bulk of solution first made up, which may amount to (perhaps) two gallons, and so keep using it over and over again until the whole quantity ceases to give good results; I then send it into the printing-room, where its strength is raised by the addition of silver to sixty or seventy grains per ounce, and it is then used up for exciting albumenized paper.

In developing, it is a good plan to have a saturated solution of iron and the acetic acid and water in a separate bottle, so that you can at once alter the strength of the developer to suit the particular class of subject upon which you are operating.

The collodions in the market are so numerous and so good as to render any especial naming invidious; most of them, however, possess special and different characteristics, and it will be found advantageous to mix them in various proportions to suit the particular modes of lighting adopted in different studios.

I have done a fair share of out-door work, and for views within a radius of a mile or two of the operating-room I have invariably found that the best plan is to send for a cab, prepare two or three plates of different sizes, put them into camera slides with blotting-paper at the corners, and two or three thicknesses of the same, well damped, on the back; get into your cab, go round to the points of view, expose the plates, and bring them home to develop.

I have frequently been absent two hours on these occasions, and always found the plates develop satisfactorily; it is necessary, though, that the slides themselves should be well wiped out with a wet sponge, and be kept in a horizontal position before exposure, and a vertical position after it.

There are a few other points to be noted about the conduct of a photographic business as a business, which may be worth noting. First, cultivate the children's portraits; no doubt they are troublesome, but patience and good temper will generally lead to success, and you will have secured your passport to the good offices of the parents.

Secondly, be very liberal in your business; never raise the least objection to retakes; never mind if your clients seem a little unreasonable: no one is without a little vanity, and as very few people see themselves as others see them, they are generally a good deal disappointed when the photographic view of their physiognomy is presented. Make allowances for all this, and treat your customers with courteous liberality.

Have the regulations of your studio and general business clearly drawn up and notified, and having carefully considered that they are absolutely necessary, *insist* upon their due observance. See that all the work sent out is as good as can be achieved; let it be real and honest, the prints well washed, and the pictures rendered as permanent as any known means will permit.

A most important element in success is that the conductor of a portrait business should be not only an artist, but a gentleman. In the early days, when photography was something like the Cave of Adullam, a refuge for the destitute, there were but few of education or position in its ranks. Now the case is different, and the principal of a business should be a man of sense, quick and active, with a knowledge of character, also a man of education and some scientific knowledge, as well as having an artistic faculty for readily seizing and adapting the materials presented to him. It requires all these, assisted by politeness and courtesy, to enable a man to reach the front rank of a profession which is, now-a-days, both honourable and lucrative.

#### REFRESHING SILVER BATHS.

BY FRITZ HAUGK.\*

WHEN a bath is out of condition, and is not very old, the solution may easily be rendered quite serviceable again, in two ways: either by the addition of some fresh nitrate of silver solution, or by adding gradually a few drops of permanganate of potash solution. But when the bath is a very old one, a more thorough and radical mode of treatment becomes necessary.

For some time past, I have proceeded to remedy my baths according to a plan of my own, and I have found the most successful results to follow from it. It is as follows: In the first place I pour the solution from the dipping bath into a suitable vessel, and evaporate it to dryness. The residue is then heated, and fused at a moderate heat, until it begins to froth and flow in a stream. As soon as the residue has cooled, I weigh it carefully, and a half of it is dissolved in twenty-four times the quantity of distilled water. The solution thus obtained is filtered, and the clear liquid is now poured upon the remainder of the precipitate, and the latter dissolved, so that the distilled water is only in the proportion of one in twelve.

A second filtration of the liquid now ensues, but in carrying out this operation it should be borne in mind that a fresh filter paper must be made use of. After filtering, the solution is poured back into the dipping bath, and is ready for immediate use.

The precipitate must not be over-heated. The solution will work brilliantly and uniformly. If too much heat has been applied, it is probable that the bath solution will require the addition of a little acid.

## WINTER PHOTOGRAPHY.

EVERY reader of Lieutenant Chernside's interesting statement of his photographic experiences in the Arctic regions has probably recognised in them a magnified image, something like, in principle, to the well-known spectre of the Brocken—of occasional results in his own practice of photography under the dreary conditions of an English winter at its worst. The "hard, grey weather," which Charles Kingsley exults in as producing hardy Englishmen, the photographer knows full well produces hard, grey negatives, when it permits negatives to be produced at all. At the outset of his paper, Lieutenant Chernside, who had naturally taken an interest in examining all accessible examples of Arctic photography previous to commencing his own work in that direction, states that all the specimens he has seen are marked by the same characteristic defects, "a want of density and dark mottled stains," the precise defects which, in an excellent article by Mr. J. W. Swan, written some time ago, on winter photography, were indicated as the specific faults of winter negatives in England, and with which almost every photographer is familiar who works under the worst conditions of the season, without some effort to ameliorate them.

The photographic winter difficulties arise from two causes: the prevalence of a low temperature, which is always unfavourable to chemical activity, and the weak non-actinic character of the light. The first difficulty may be largely, if not entirely, overcome by artificial conditions; but the second can at best be only ameliorated. All photographic operations, it should be remembered, will be slower in winter than in summer. The collodion will set more slowly, and if the plate be immersed before it is fully set, streaks and arborescent markings will almost certainly be the result. The conversion of the salts in the collodion into bromide and iodide of silver takes place more slowly than in warm weather, and if the plate be removed too soon it not only contains a more superficial layer of sensitive salts, but it retains a larger proportion of free bromide and iodide, which act as powerful restrainers during development; and both causes tend to the production of a thin hard image. The amount of the light is not only much less, but its quality is much poorer and less actinic than in summer. According to Professor Roseoe, the total amount of photo-chemical action on a day in mid-winter is twenty-five times less than on a day in mid-summer; and, as Mr. Swan pointed out in the article to which we have referred, allowing for the variation in the length of the days, this shows that the chemical intensity of the winter light is ten times less than that of summer light. Hence where an exposure of twenty seconds would be sufficient in summer, two hundred seconds, or more than

three minutes, would be required to secure a similar effect in winter, even on the supposition that length of exposure would always compensate for inferior quality of light, which is more than doubtful. The feebleness of the light and prolongation of the exposure involve a variety of other troubles. When light is the strongest force acting on a sensitive surface the image is formed before any accidental adverse influence comes into operation, and a good negative may be secured in spite of some imperfect chemical conditions. But when the light performs its work feebly, all adverse influences are relatively more potent. Traces of impurity in the free nitrate of silver on the plate, traces of impurity (chemical or mechanical) in the collodion, any imperfection in the surface or cleanliness of the glass; in short, any cause which might initiate or modify chemical action has time to come into operation, and thus streaks, stains, and defects of various kinds prevail. The action of the developer is generally singularly tardy in winter. This appears to have been one of the most troublesome of the difficulties encountered by Lieutenant Chernside in his arctic operations. His experience as to the inactivity of a new solution, and the increased reducing power which the solution gained by keeping for a few days, are so singular that we repeat them here in order to point out the importance of repeating and verifying the experiment under more favourable conditions for observation. Speaking of the iron solution, he says:—

The solutions were therefore made up with water at temperatures from 90° to 120° F., and kept in the engine-room; and we found that under these conditions the developer would always act, provided it had been kept for a few days. With freshly made solutions but little result could be obtained, and the deoxidizing action of a ten-grain developer that had been made up for a week was stronger than that of a sixty-grain solution, unless the latter had been made up for at least thirty hours. The solutions were not used until of the dark, clear colour of brown sherry, and, once of that colour, seemed to keep indefinitely; whether this was due to persulphate of iron or not, no rustiness or want of transparency ever appeared. Until it had been made up for twenty-four hours the solution was clear and colourless, after which the colour gradually deepened, and it seemed of full power when from four to six days old. When used cold, or at the temperature of the surrounding air, however evenly poured over the plate, a spotted, mottled staining was in places always observable, as if the constituents of which the solution was composed were no longer held in intimate mixture. The refusal of the solution, when still colourless, to act at any ordinary temperature was not perceptibly altered by reducing the amount of acetic acid contained in it, which was diminished to a point at which the formation on the film of a dark purple scum showed the necessity of its presence; nor did the addition or withdrawal of alcohol within certain limits produce appreciable effects, so that we concluded that a sluggishness of action was induced by the climate, only to be overcome by mixing the solution and maintaining it at a high temperature. The proportions used in the solutions were—

Protosulphate of iron	...	...	10 to 60 grains
Glacial acetic acid	...	...	6 to 18 minims
Alcohol	...	...	10 to 30 "
Water	...	...	1 ounce.

Of course stronger developers were applied to films that had been only exposed for one or two seconds or less, or where, as is often the case in Arctic regions, from the contrast of the objects in the view, their adoption seemed advisable. With instantaneous views, under disadvantageous circumstances of light, we found sugar of great use in bringing out the image; it was simply pounded, and a few grains placed in the beaker containing the solution with which the plate was about to be flooded; this substance seemed to stimulate the action of the developer, and also to increase the density of the deposit.

A very prevalent belief obtains amongst many operators to the effect that iron solutions act more satisfactorily some time after they are mixed, and especially as to the advantages gained by keeping a saturated solution in stock ready for dilution; but, so far as we remember, we have not found any former record of increased activity in the reducing quality of the solution as the result of such keeping, the partial oxidation of the iron salt generally tending to reduce activity, the peroxide acting, in fact, in some degree, as a restrainer. The experience of Lieut. Chernside appears, however, to have been constant in this

respect, and the fact is well worthy of attention and of experimental verification.

The chief control which the photographer possesses over winter conditions consists in his power to raise the temperature of his operating-room and of his chemicals to something like summer heat. Many photographers undertake this in some partial degree, but not thoroughly, and the result is not satisfactory. It is not difficult to warm the nitrate bath and developing solutions, and this is something: but it is of vital importance that the operating-room and studio should also be warmed, so as to maintain in the atmosphere and all the solutions a temperature as little short of 60° Fahrenheit as possible. Inequality between the temperature of various solutions, and between various solutions and the atmosphere, is in itself a source of many difficulties which may be avoided by the maintenance of uniformly warm conditions. The difficulty of doing this need not be great with the various modern appliances for simple, efficient, and wholesome warming which exist. Of the excellence and efficiency of George's Calorigen we have already reported in these pages. To the excellence of Brown and Green's stove a correspondent has recently referred, whilst ordinary stoves and ordinary fire-places are in many cases available.

In relation to winter light the photographer can do little. A flood of weak light in the studio will not equal, in result, a small amount of good light illuminating the sitter only. Clean windows, so that no portion of the light shall be shut out by a film of dirt; reflecting screens, to direct as much light as may be needed into dark shadows; the auxiliary action of diffused light, white or coloured; rapid lenses with full aperture; and similar appliances, may do something; but, on the whole, the photographer must rely chiefly on the perfection of his chemical conditions, and the aid of artificial warmth, to combat, if not overcome, the troubles of winter photography.

We have not adverted to the printer's troubles during winter; but we may remark, before leaving the subject, that in nothing is the aid of a little artificial heat of more importance than in toning and fixing prints, the solutions for which should in no case be used at a temperature less than 60° Fah., and might, in many cases, be used with advantage still warmer.

### SENSITIVE COLLODION FOR THE WET PROCESS.

At a recent meeting of the Photographic Section of the American Institute, Mr. P. C. Duchochois gave details of a method of working the wet process giving unusual rapidity, the chief element of sensitiveness consisting, as he alleged, in the quality of the pyroxyline, which, moreover, gave a film free from texture. This is prepared as follows:—

"To prepare the pyroxyline mix in a thick porcelain mortar, heated to about 120° F., one pound of pure dry saltpetre with one and a half ounces of water and twenty-six fluid ounces of sulphuric acid at 66° Baumé. I immerse *immediately*, by small quantity at a time, as much cotton, well pulled apart, as the mixture will cover, taking care before each addition that the cotton immersed be well impregnated with the acids. During the operation the vessel should be covered, and the cotton turned over several times, in order to insure an even combination. The temperature should not be allowed to fall below 140° to 150° F. After twelve minutes of immersion the pyroxyline is rapidly washed in water, until the blue litmus paper shows no trace of acidity.

"It is then treated by a very diluted solution of bicarbonate of soda, washed four or five times, and, when thoroughly dry, immersed in alcohol during twenty-four hours.

"It is afterwards washed several times in alcohol, and allowed to dry spontaneously.

"The organic pyroxyline for dry plates and emulsion processes is prepared by the following formula:

Nitric acid at 41° Baumé	...	4 fl. ozs.
Sulphuric acid 66° "	...	5 "
Temperature	...	150° F.
Time of immersion	...	10 minutes.

"For dry plates the washing in alcohol must be dispensed with, as its object is to dissolve the nitro-glucose which is necessary in this pyroxyline.

#### "The Collodion

is composed of one equivalent of iodine and one-half equivalent of bromide dissolved in 30 fluid ounces of plain collodion. The formulæ stands thus:

#### "Plain Collodion.

Ether conc.	...	13 fl. ozs.
Absolute alcohol	...	4 "
Pyroxyline	...	200 grains.

#### "Bromo-Iodide Solution.

Alcohol at 90°	...	12 fl. ozs.
Iodide of cadmium $\frac{1}{2}$ eq.	equal	92 grains.
Iodide of sodium $\frac{1}{2}$ eq.	equal	75 "
Bromide of sodium $\frac{1}{2}$ eq.	equal	52 "

Mix. With well settled plain collodion one half equivalent of iodide of sodium can be substituted for the iodide of cadmium, and the collodion used a few hours after its preparation. It gives somewhat more intensity, but is not so stable, and will be rapidly decomposed with most samples of ether."

Instead of using a large quantity of silver solution, as is generally recommended, Mr. Duchochois recommends a small quantity and frequent renewal. The developer employed is novel in some points. It stands as follows:

#### "Developer.

Water	...	8 pints.
Sulphate of iron and ammonia	...	5 ozs.
Sugar candy	...	2 "
Sulphuric acid...	...	1 fl. dr.

"Boil the solution for about five minutes, add one and a half pounds of acetic acid, and filter."

### NOTES OF OBSERVATION AND PRACTICE.

BY AN EXPERIENCED OPERATOR.

WOODEN TRAYS FOR SILVER SOLUTIONS—TRANSPARENCIES FOR ENLARGEMENT—DISTORTION THROUGH THE SHRINKING OF PAPER.

[UNDER this head—"Notes of Observation and Practice"—our contributor, one of the most skilled and experienced of London portraitists, will from time to time place before our readers in brief form the results of his own extended observations and practice, as bearing upon topics of current interest to photographers, especially those belonging to the studio and dark room.—ED.]

*Wooden Trays for Silver Solutions.*—In Mr. G. Crough-ton's excellent article on enlargements he states that he uses for a bath a tray of wood, lined with brown paper which has been soaked with shellac varnish. No doubt this answers well, but to those who either cannot procure the varnish, or who do not care about the trouble of varnishing, we would recommend the substitution of the best American cloth, such as is used for upholsterer's work, for the paper. This can be used without any preparation, and, by careful folding at the angles, can be laid in the tray in one piece, thus avoiding joints, which are always dangerous. The edges should be turned well over, as, if the solution reaches the back of the cloth, it will speedily destroy it. There is one important drawback to dishes lined in this way; namely, their liability to injury from the sharp corners of the plates. A large plate accidentally dropped will make a hole which it is difficult to repair. For this reason we always use a wooden tray, coated with the best pitch, which answers to a charm. The tray should be made very hot before a coke fire, and some

boiling pitch, in which has been dissolved a little fine tallow, poured into and well spread over it. All inequalities may then be smoothed out with a hot flat-iron, an application of which will at any time stop a leak if it should occur.

*Transparencies for Enlargement.*—Mr. Crompton has undoubtedly "hit the right nail on the head" when he lays the utmost stress upon the quality of the transparency. Fifty per cent of the transparencies made by beginners, are under-exposed, as well as under-developed. We prefer to intensify, rather than tone, by pouring over the plate the ordinary pyrogallic re-developer, after fixing. This does alter the tone, and renders the deposit very non-actinic, while it is safer in many respects than the bichloride of mercury, which is so very liable to act unequally.

*Distortion through the Shrinking of Paper.*—Photographers will do well to devote some attention to this subject. So long as only small pictures were produced this distortion would be of little import; but now, when attention is chiefly devoted to large work, this is a matter which must be considered. No doubt this defect will be most fully developed in the case of solar camera prints, in which the paper is exposed and receives the impression when expanded, while the minimum of evil will be reached in collodion transfers, which are supported upon glass until dry.

Our plan is to apply the bulk of the mountant to the surface of the cardboard, only slightly damping the picture itself, and that as rapidly as possible, by means of a large sponge. The picture should be secured by placing upon it a sheet of thin cardboard, and well rubbing upon this with a large cloth. Freshly made starch, which has just become cold, answers better than anything which we have tried.

#### FRENCH CORRESPONDENCE.

THE year which has just passed away has been full of activity, so far as photography in France is concerned, and if the efforts made have not actually given birth to any new discovery of great originality, they have at any rate been instrumental in producing numerous improvements of great importance to the future of the art. 1873 will be, let us hope, an era from which we may date an advance in the progress of permanent printing methods, towards which our aim has always been directed since the origin of photography. There are at the present moment, without counting the ateliers of the War Office, those of MM. Goupil, Baldus, Dujardin, Anand Durand, Lafman et Lourdel, now existing, and three new establishments where printing with greasy ink is exclusively carried on, those of MM. Geymet and Alker, Flourey Hermagis, and Javel. Photography in pigments, as I have already stated, has now quitted the laboratory of the amateur to enter that of the professional photographer.

If this transformation is the result of a general movement, it is but just to recognize that the progress has been in large measure due to intelligent men who have prepared the way and facilitated the advance. The claims of M. Geymet in this respect ought particularly to be recognized; for, without pretending to alter in any way the original methods, he has rendered them especially practicable.

At the beginning of 1873 M. Geymet published his treatise on photo-lithography, and he presented to the Photographic Society of France proofs which produced a great sensation. Soon after came M. Fortier, and then M. Javel, who on their side demonstrated that the problem could be resolved in various ways; for whilst M. Geymet employed a lithographic stone, M. Fortier pulled his prints from glass, and M. Javel from metal plates. Afterwards there was published, it may be remembered, the fine work, called the "Album Contemporain," printed by means of papyrolith by M. Hermagis.

At the same time M. Marion, whom we lost in the same year, made known various practical improvements in carbon

printing, and published the two ingenious processes called Mariotype by pressure and Mariotype by contact.

The public demonstrations made by MM. Geymet, Jeaurenand, and Gobert considerably startled those orthodox disciples of the art, by the fact that the new processes enjoyed one advantage over the old ones which was not to be despised—viz., that of simplicity in their manipulation.

A communication of high interest was also made during the course of the past year by M. Leon Vidal. His memoir on polychromic photography contains the germ of a veritable revolution in the art. The results obtained by this eminent experimentalist prove that his method is not merely pure theory, but that one may really produce by the superposition of monochrome transparencies derived from different coloured mixtures made up like carbon tissue, the same effects as are secured by chromolithography. An atelier to carry out this subject in a commercial manner has been established at Marseilles.

At the present moment, too, M. Lavoelic, of Constantinople, has obtained similar results to those of M. Vidal by successive printings in the press, the pictures approaching even more nearly still to chromo-lithographs.

The production of clichés has made so much progress during the last twenty years, and we have arrived at so great a degree of perfection, that there is, in truth, but very little remaining to be done. Nevertheless, we have seen during the past year several methods brought forward, which may, at least, be considered as ingenious modifications of processes already known. Emulsions, notwithstanding the efforts of many experimenters, have been but slightly recognised in this country; but, on the other hand, the practice of alkaline development is becoming very widespread.

Dry plates are beginning to take a place in studios where before their presence was refused. The publications of M. A. de Constant-Delessert have contributed, in a great measure, to bring about this favourable change. The two new wet processes published by M. Sutton appear to have numerous partisans.

Enlargement processes have made much progress since last year. The plan which consists of retouching, not the cliché, but an independent glass plate, having generally a matt surface, and coated with an adhesive substance, permits one to obtain pictures much superior to those hitherto secured by enlarging methods.

Three works relating to photography have been produced during the course of the past year. They are the "Manuel de Collodion Sec au Tannin," by M. le Comte Courten; "Le Collodion à Sec mis à la Portée de Tous," by M. de Constant; and the sixth edition of M. Van Monckhoven's book, entitled "Traité Général de Photographie."

I spoke just now of the retouching of negatives. We all know that the admirable portraits which are produced in the studio of M. Adam Salomon, and which are truly works of art, owe a large portion of their beauty to his skilful method of retouching, to which every cliché of his is subjected. A very great number of portraitists visit this eminent photographer and sculptor, and ask his advice in the matter of retouching, showing M. Salomon pictures which are often deteriorated by unskilful after-manipulation. The following is the plan adopted by our friend in the matter, and one which he particularly commends to all photographers:—After having varnished the cliché in the ordinary manner, he varnishes with a matt varnish, or with a slight film of gelatine, the reverse side of the negative, and it is upon this surface that the most important part of the retouching is done, the negative film itself only receiving a very slight manipulation, such as may be required for stopping out freckles, pimples, and the like.

In this way the value of a cliché is not jeopardised by retouching in a manner which may be irreparable, and prints are, moreover, secured of exquisite softness, which combine in themselves perfect sharpness and vigour.

ERNEST LACAN.

M. CONSTANT ON DRY PLATES.—No. 3.

*Concerning Lens and Exposure.*—Everybody has his own ideas regarding the kind of lens to use, and I must admit that my own have varied much in the matter. Nevertheless, I am now of opinion that a globe lens, when one can be obtained good and powerful, has much depth of focus, and reproduces aerial perspective in a very satisfactory manner. I know that there are many more rapid instruments, and that the globe lens requires a somewhat lengthy exposure, and centralises more or less; but, at the same time, it does not distort; it marks the various planes, and for most cases a pose of two or three minutes is enough.

In this respect, I may explain that in landscapes containing much distance, and which are well lighted, my exposure is often reduced, without inconvenience, to thirty seconds; but with views of country close at hand, with dark verdure and with the foreground in the shade, to give an exposure of three minutes is always a prudent precaution. With this new process, therefore, and with the aid of alkaline development, the average exposure is twice as long as when one works with wet plates, and, according to the lights and contrasts, one may reduce to half the amount, or augment as much again; but with the dry plates the best rule is always to give full exposures, and thus facilitate the development. The globe lens that I employ has a focus of nineteen centimetres, and, with an ordinary aperture of six centimetres, it will cover a whole-plate completely.

*Development.*—With several of the dry processes I have found great advantages to accrue from development with iron, the clichés being more fresh and transparent. I have even found that the dry film, moistened by a bath of ammoniacal water, and well washed under the tap, will proceed to develop very regularly by employing a five per cent. solution of iron, with the addition of gelatine. But this development is rather more difficult to conduct, and an exposure of a notably longer duration is required than with alkaline development, which enjoys the material advantage that it may be employed strong or weak, in such way as to correct the errors of exposure. A reproach may be made against alkaline development, to the effect that it produces images in which the softness is often exaggerated; but this defect (if it be one) becomes a virtue when albumen is used, for this substance has a tendency to yield hard pictures. It is alkaline development that I have chosen for my new process, and among the many formulæ which have been cited, I have chosen the one mentioned by Messrs. Mawson and Swan in a recent publication. The following is the composition of the three solutions necessary:—

No. 1.—Alcohol	...	...	30 cubic centimetres
Pyrogallie acid	...	...	4 grammes
N. 2.—Distilled water	...	...	30 cubic centimetres
Fresh carbonate of ammonia	...	...	1 gramme
No. 3.—Distilled water	...	...	40 cubic centimetres
Bromide of potassium	...	...	1 gramme

After the exposed plate has been put into a bath filled with ordinary water, where it must remain for a couple of minutes, it is put gently under a water rose, and is then placed upon a plate-holder. Then, proceeding to its development, there is poured upon it (supposing it is of whole-plate size) thirty cubic centimetres of water, together with twenty or thirty drops of No. 1 solution, which ought to complete the softening of the film commenced by the water. This solution is flowed over the plate for a minute or two without producing an image. To the liquid is then added ten drops of No. 2 solution, and two or three drops of No. 3 solution. This mixture thrown over the plate at once produces a result, and the image comes up with such vigour that very often the employment of silver as an intensifier is quite unnecessary; for if the details of the

picture fail to appear, one may add a few drops of No. 2, or employ a fresh mixture, in which the brouide solution is somewhat lessened, or left out altogether. If the exposure has been sufficient, five minutes ought to be enough for completing the development of the negative. If the cliché lack vigour, it must be intensified with a pyrogallo-citric acid solution, containing several drops of neutral nitrate of silver; but the intensifying should be conducted with prudence, so as to prevent the film becoming too opaque.

*Fixing.*—When the development has terminated, it is followed with a thorough washing of the film, and the plate is then put into a bath containing a saturated solution of hyposulphite, often renewed. One need not fear to prolong the operation of fixing, and in every case not to terminate it until every trace of iodide of silver has disappeared, even on the margin of the plate. With dry plates it is exceedingly difficult to get rid of the iodide, and often, when printing, one does not observe that there is any remaining, and opaque patches are then inevitably caused. It is scarcely necessary for me to add, that after the fixing a very thorough washing of the plate should take place, which should, moreover, be carefully conducted.

*Retouching and Varnishing.*—As a rule, dry plates soon lose their moisture, but, nevertheless, it is necessary to see that they are properly dry before they are varnished, for the least trace of moisture will produce irreparable patches and stains. A varnish which does not present a hard and brilliant surface will not bear printing from. Moreover, certain kinds of varnishes do not well support change of temperature, and either cause the loss of the negative, or necessitate a delicate and troublesome mending. It is important, therefore, to secure a varnish which may be thoroughly relied upon.

Without retouching landscape negatives, as done in portraiture, there are, in photography, many things which it is impossible to reproduce properly without employing the paint brush a little, or having recourse to a little ingenious artifice. Thus, besides the actual retouching, it is possible to varnish the back of the cliché and work upon the surface with a stump or with a red chalk; or, instead of varnishing, one may fix to the glass a little transparent paper upon which is lined cloud effects, or a dark surface, to preserve the negative from being printed through too much in those parts which lack detail. Outlines may also be applied to mark the lines of a lake or of the horizon, care being taken in the printing to preserve parts of the negative from printing too much. All these aids, if practised with intelligence, will be found to do good service. In general, printing in the shade is better than printing in the sun, but if only sunlight is available, then it is well to place a sheet of ground glass upon the printing-frame, the matt side uppermost, an indispensable precaution, indeed, when the cliché has been retouched or stopped out.

*Plateholders to obviate touching the glass with the hands.*—Every one knows that the thumb at the edge of the plate, and the heat of the fingers underneath the glass, are a continual source of spots and stains of every description.

Many kinds of holders have been devised to overcome the difficulty, the ordinary pneumatic holder being that generally employed; but in this case the operator's wrist is

underneath the plate, and there is a good chance of the liquid running up his arm. This defect has been obviated by employing an arm of suitable length, which is fixed to the bottom of the plate-holder. The plate can then be turned in every direction towards the hand used for pouring the collodion. Most instruments require the fist to be under the centre of the apparatus—a most serious drawback. I have devised an instrument much less costly than a pneumatic holder, which leaves, moreover, the cuff of the operator free, and permits of the manipulation of the glass very easily. It is made of light wood, and varnished. A, handle, thirty to forty centimetres long; B, supports fixed to the handle, and made of the requisite size for holding the plate; C, notches or grooves to retain the plate.

### Correspondence.

#### DISSAFFECTION IN THE LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Before making a few general remarks upon the above subject, allow me to correct a statement made in your reply to "A Country Member" in the NEWS of Dec. 24th, 1873, that "no alteration in the laws had been proposed by anyone, we believe, for upwards of a dozen years.\*" If you will be so good as to refer to the NEWS of Feb. 16th and March 15th, 1872, you will find an alteration to Law IX, in consequence of a letter I wrote to the Council, and referred to by the chairman at the annual meeting, Feb. 13th, 1872, and made law at a special meeting held after the ordinary meeting, March 12th, 1872. The alteration was to the effect that members joining the society in Nov. or Dec. should be entitled to full membership by payment of the guinea entrance fee only; and the result was, that after the next exhibition no less than twenty-three new members were elected at the first ordinary meeting, a clear proof that this alteration of the laws was of a most salutary character; and it may be that these can be still further improved to meet the wants of this progressive age.

May I ask your readers, Mr. Editor, to read an excellent letter from Mr. Hudson, that appeared in the NEWS of the 13th Dec., 1872, and who was one of the twenty-three new members elected on the 10th Dec., 1872.

After bearing testimony to his own observation, even as a non-member, of the beneficial action of the Society, and declaring his resolve to join at once, Mr. Hudson remarks: "Surely, sir, we ought to strengthen the hands of the council of the Society, who take no pecuniary remuneration for their arduous duties, but who certainly, at the very least, ought to receive the grateful commendation of those for whom they labour;" and he concludes by saying that he shall feel himself honoured by association in membership with "men who have the good of the profession (and not their own ends) at heart."

Having been connected with photographic societies myself for fifteen years, and with the London Photographic Society for a great part of this period, and having known the North London Photographic Society in its best days, I feel I am, in some measure, able to judge of the cause of their rise and decline; and my humble opinion is, that the chief detriment to their greater success is the small interest taken in them by the independent members themselves. It is always easy to blame councilmen, secretaries, vice-presidents, and even presidents, but is it not wiser to look at home? All the grievances as at present brought against the Society (whether they be real or not, I am not going to pass an opinion) arise entirely from the apathy of the members, many of whom are continually grumbling, but never act. Why have they always submitted to the dictation of the council? They have full power by Law VII. to nominate fresh councilmen once a year, but the January meeting generally passes off without any action on the part of independent members, and when February comes it is too late, and then John Bull, as usual, grumbles. The January meeting is often a very thin one, and us photographers are known to be gay and jovial, it is very probable they are differently employed during the long evenings of this happy month; but surely this is no fault of the council, who are compelled by the laws to be ready provided with a list a month in advance. How is it that in January there is often a paucity of papers, and in May a plethora? How is it independent members take so small a part in the discussion of the subjects brought forward? And how is it we do not have

papers on more practical matters, such as would enlist the interest and sympathy of all the members? Surely there is no need for such reticence; all have much to learn, and all should be willing to communicate their mite. Let us put aside this apathy, and, instead of grumbling, put our shoulder to the wheel. Let us see whether we cannot improve the tone of our meetings, and pour fresh life into the Society, by helping, both by regular attendance and an active interest in its working, and also by inducing others to join. Is the collodion process perfect? I answer No! How is it we cannot take portraits in smoky towns in winter under thirty seconds? Are we working in the right groove to attain instantaneous photography in all weathers (except foggy)? Are we always to have the trouble of waiting whilst plates are sensitized in a nitrate bath? Have we got the best developer of the latent image that chemistry and science can give us? And is the nitrate bath to be a constant uncertainty, always on the change, and continually requiring rest, and even stronger measures? Is an organic substance in the iron developer really an advantage, or only an idea? Is a preliminary coating of albumen under the collodion film an advantage, or simply an expedient for encouraging laziness and the using of inferior glass? All these questions, and a hundred more, might fairly be discussed, and would certainly draw forth some valuable information. The art is not sufficiently advanced as yet to permit us to lie down upon our laurels, or even to waste time by special meetings to appoint fresh councilmen, when there is every convenience in the laws of the Society for this to be done in the regular and ordinary way.

The "London Photographic Society" has been established over twenty years, is the representative society of the art for this great nation, sometimes called a nation of shop-keepers, &c, but I do hope we shall not waste valuable time in talking shop, and by holding special meetings, unless quite necessary. I do hope all those who have complaints to make will come forth boldly and make them, and let all be cleared up as quickly as possible, and then work together with one grand desire at heart, namely, "the advancement of the art we so much love."—I am, dear sir, yours truly,  
GEO. HOOPER.

#### THE PHOTOGRAPHIC SOCIETY.

SIR,—The note of your correspondent, relative to the requisition for a special meeting of the Photographic Society of London, most curiously mis-stated the facts of the case. As one of the promoters of the requisition, and one of the first signers, I am able to say that the allegations in that note are entirely false. The requisition was drawn up by three members of the present council, not one of whom had been a competitor for any award at the exhibition, and of whom, only one—myself—was to retire at the next election; and that my course had nothing to do with my being retired will appear from the fact that the movement had begun before the selections for retirement were made by the council, my name being included amongst the retired in consequence of my having taken part in this movement through a letter published in the *British Journal*, advocating it. Of this I have ample assurance. Of the other signatures, three at least were worthy recipients of a medal, and only one, so far as I know, is a disappointed competitor.

The object of this requisition is simply to secure to the Society at large the control of its own affairs more completely and with less trouble than is possible by any operation of the present method of electing officers. Minor objects may have differed in the view of different signers, but all were agreed in this. Some were opposed to any change beyond that involved in a renewal of the council by thirds every year; others, amongst whom myself, regarded it as important that all officers, including president, should be changed at each election, and the honours of the Society thrown open to all of its members, as well as fresh energy infused into the action of the Society, and new influences brought to bear on it. I consider that such a change is the only method of awakening that interest in the proceedings of the Society which is necessary to its efficiency, and is now wanting.

So far as I and those directly associated with me in the movement are concerned, I can respond for our action as being entirely free from any personal motive, any resentment or ambition, and entirely animated by regard for the good of the Society, and the interests of photography. I am not acquainted with all the gentlemen who signed it, and cannot answer for them, but simply for those who originated it.—Yours truly,  
W. J. STILLMAN.

[All well-wishers to the Society would feel glad to be convinced that the movement to which Mr. Stillman refers is not influenced by personal motives, and will probably be willing to accept our correspondent's assurance that he is not consciously under the influence of such motives; but we think that he is curiously

\* We should have said no organic or important alteration.—Ed.

unaware of some facts, and that he unconsciously states others in a manner which must mislead. Various communications which have reached us on this subject we have not published because they were of a personal character, the statements in which have varied from those of Mr. Stillman, the paragraph to which he refers being but a summary of a communication giving fuller details coupled with names. One gentleman was named as actively canvassing who was certainly not a member of the council. Mr. Stillman states that the requisition was drawn by three members of council. It was only signed by two, and we must confess that it seems to us a practical solecism for even two members of council to send a requisition to themselves, asking for unusual action to obtain that which, as members of council, they had simpler means of initiating. We are placed in a difficulty by Mr. Stillman's statement that his name was placed on the retiring list of council because of a letter he had written, as, having been present at the council, we know this is not true; but, as a member of council, we hold it a breach of confidence to speak out of the council-room of the transactions. We may, however, say that it was simply for the usual reason of irregular attendance at council meetings that Mr. Stillman's name was placed on the retired list. If Mr. Stillman's "ample assurance" of other facts stated in his letter be based on no better ground than this fact, we fear he is labouring under misconception. His statement that three of the signatories were recipients of a medal is at least misleading, as it would suggest that each of these three had received a medal, whereas the three gentlemen constituting one firm, and receiving one medal, stand as three persons in the signatures. So far as the aims of the requisition are concerned, any step which shall lead to increased efficiency and interest in an already efficient and interesting Society shall have our cordial support and co-operation; but we must confess that the form which this movement has assumed seems to carry on its face certain elements of disaffection and antagonism, quite as likely to lead to heart-burnings as to reform.—Ed.]

THE PHOTOGRAPHIC SOCIETY.

SIR,—In thanking you for answers to my recent questions, I wish to make a few more observations. From a paragraph in your last, I glean that the easily imputed, and, I regret to say, commonly imputed, charge of personal feeling is brought against those who are working to secure a modification in the laws of the Photographic Society. The possibility of such an imputation is easily removed, and should be removed at once. The case, as I understand it, stands thus:—It is alleged by the non-contents that the council are ambitious, and, wishful to retain the power of managing the Society in their own hands, that they constantly secure the re-election of members of their own body in order to retain that power. It is alleged, on the other hand, that the leaders of the agitation are influenced by selfish motives, being anxious to obtain a seat at the council themselves; and if this were so, lookers-on would be apt to think that, so far as the good of the Society is concerned, the difference between ambitious officers *in esse*, and ambitious officers *in posse*—between ambitious actual councilmen, and ambitious would-be councilmen—is probably much the same as the difference between Tweedledum and Tweedledee, except that those in office have experience, and those anxious to be in have not.

But I have a suggestion to make to the gentlemen who are leading this agitation, by adopting which they may place their motives beyond suspicion, and by which they will, I feel certain, secure the adhesion of all independent members of the Society. Let the leaders of this agitation—say all who have signed the requisition referred to in your last—pledge themselves not to accept office in the first year after the passing of the reformed laws. By such a course they will prove themselves to be actuated by a desire for the good of the Society, and not by personal ambition. If, on the other hand, they seek to obtain the office which they blame the existing council for retaining, they must rest under the suspicion of using a pretence of desire for public good merely as the stalking horse for private ends or personal ambition. Should they pledge themselves not to accept immediate office, I, and I believe many others, will attend any meeting called, and support their endeavours to place the rules on a wider basis. Should they decline to pledge themselves not to accept office, I for one shall also decline to be made a cat's paw to serve the purposes of a few discontented and ambitious men.—Yours respectfully, A COUNTRY MEMBER.

DRYING DRY PLATES.

DEAR SIR,—Some time since I raised the question in your paper, "What is a dry plate?" but nothing further was said in

reply than your editorial remark that it meant, not a plate simply surface dry, but thoroughly desiccated; and the interesting letters in your issues of this and last week by M. de Constant on dry plates again leads me to ask for some more definite information.

M. de Constant suggests such methods of drying as will be only of the kind called surface dry; and he says, "The drying of the plates is a most important part of the operation."

Col Wortley says they should be dried by heat, and yet no definite temperature is given in either case. As it is understood that drying bichromated gelatine, for carbon printing, is more sensitive when slowly dried, and the sensitiveness consequently lessened in proportion to the heat employed in drying, so may it not be with bromide dry plates. If any experienced worker will give some information on this point, it would be of much advantage, I am sure, and save much of the conflicting opinion as to the sensitiveness which is really obtained in dry plate work.—I am, dear sir, yours truly, F. R.

THE NEW LIME BALL.

SIR,—From the PHOTOGRAPHIC NEWS, I see the lime ball which I invented and introduced here some time ago has caused some little discussion, and many have expressed the hope that it would ultimately prove successful. Experiment, followed by discussion and expression of opinion, is the only way to bring out its merits and defects, by plainly showing what is to be improved, as well as what is already perfect, so that I hope there will be still further trials and further expressions of opinion in the NEWS and otherwise.

I have lately changed or modified both the formula for the balls, and the way in which I manipulated them, so as to avoid defects which, quite apparently to myself, were inherent in both the theoretical and practical part of the original process. I at first used the fine carbonate of lime as the basis, thinking it would yield a more uniform mass, and therefore less likely to split under the heat than the coarser "prepared chalk," and with the idea also that the finer preparation and whiter ball gave a better light. After many experiments I believe I am mistaken.

Making the balls now with the ordinary prepared chalk, I find, after many experiments, that I have not only as good a light, but also a very superior ball, it being harder and more dense, as can well be understood; whilst in all my experiments I have not had one ball that has split with me. They now pit very little—certainly not more than the ordinary lime ball—and they have frequently done duty twice over. I do not wish, however, to uphold them on this last merit; they do well if they serve once, and all I claim for them (and after all it is the one grand feature) is, that they are a ball which will keep under exposure for months or years, and at the end be as good as at first. As to the manipulation of them, I mass them as formerly, but now put the paste into moulds. This gives them a more symmetrical appearance than formerly, and also prevents them cracking in the drying. In the whole process, I need scarcely say, there are little niceties to be observed which can only be gained by experience, but which need present no obstacle to their being manufactured by any one.

I along with this send you one or two for the purpose of showing to any one interested, and I will, further, be glad to communicate with any one, either through the columns of the NEWS or otherwise, as to experiments either with the manufacture or use of them.—I am, sir, yours, &c., WM. GILMOUR.

[Mr. Gilmour has favoured us with some examples of the lime cylinders in question, which we shall have pleasure in showing to any one interested. The actual test of value in such a case can, of course, only be made in the lantern, but, so far as we can judge from appearance, these are excellent, being firm in texture and symmetrical in shape, and suggesting no tendency to crepitation or splitting.—Ed.]

Talk in the Studio.

PHOTOGRAPHY IN COLD WEATHER.—A correspondent, Mr. E. Garlick, of Downham, says:—"As I have received so much information through the PHOTOGRAPHIC NEWS, I feel it my duty to send you the following for the benefit of any one who may need it, if you think it worth inserting. By the following method I am enabled to take as good negatives on a dull day as on a bright one. My method is—first, to place the developing-cup, which is a glass measure, on the top of the stove; by the time I have prepared the plate, posed the sitter, and exposed the plate, the measure has got as hot as I can nicely bear it in my hand. I then pour into it two drachms of iron, and start developing at once. As soon as the iron is

poured on the cold plate it is, of course, chilled at once. If the picture comes up all right, why then it is all right; but if the detail shows signs of lagging behind—which is sure to be the case in dull weather—by pouring back the iron again into the hot measure, and letting it stay two or three seconds, then pouring back on the plate, it will fetch up the detail with an effect truly marvellous. By returning the iron backwards and forwards from the hot cup to the plate, you may work up the detail just as you think proper. With a weak developer and hot cup the plate is not spoiled by a few seconds' under or over-exposure, and in its effect turns dull days into bright ones."

**SHUTTER INSIDE THE CAMERA.**—Mr. S. Cornell, of Napier, New Zealand, sends us details of a shutter inside the camera, which he finds very useful, as permitting the lens to be uncovered without distracting the attention of the sitter, a point of great importance with children. A couple of grooves are fixed in the camera immediately behind the lens, in which a shutter slides just sufficiently large to cover the back of the lens. This shutter is attached to a bar at the top of the grooves by two pieces of elastic band, which, when retracted, keep it in position at the back of the lens. A piece of cord attached to the bottom of the shutter passes through the bottom of the camera, and hangs beneath the stand. When ready the operator, unobserved, pulls this cord, which pulls down the shutter, and on leaving go it is drawn back into its place behind the lens by means of the elastic bands, and so closes the lens. The plan seems to be simple and efficient.

**MUSTARD AS A PRESERVATIVE FOR DRY PLATES.**—At a recent meeting of the Photographic Section of the American Institute, the president, Mr. H. J. Newton, called attention to a new preservative for dry plates. He says:—"I have been invading the kitchen again. I mixed some mustard seed with tea for a preservative for dry plates, and found it increased the sensitiveness very much. I took two tablespoonfuls of mustard seed, and two tablespoonfuls of Japanese tea, and poured on eight or ten ounces of boiling water, covered it over, and let it stand and steep for one or two hours. I then added ten grains to the ounce of sugar of milk and filtered through cotton; made up to ten ounces, and added two ounces of alcohol. It was then ready for use. I found that the plates would give the same detail in a minute and a quarter that with the tea alone would take five or six minutes. I found, also, by crushing the mustard seed in a mortar before it was steeped with the tea, that it made a much more sensitive plate than in putting the seeds in whole; but they did not keep as well, and were nearly worthless in two weeks. With the seeds whole it required about two and a-half minutes, and the other way about a minute and a quarter exposure, while, in general, I give five minutes' exposure to tea. I afterwards tried the oil of mustard, but I found it a difficult thing to handle. It is very volatile and irritating, and makes a blister on the skin where it touches, and is trying to the eyes. I took a quarter of an ounce of the oil of mustard seed and put it in four ounces of alcohol, and it made a very brilliant negative. It had the same sensitiveness as the whole seeds."

**REMOVAL.**—Messrs. T. Ordish and Co. have removed from Newgate Street to 108, Hatton Garden.

## To Correspondents.

**A. L. T.**—The mode of enamelling you describe should, with proper care, give certain and satisfactory results; but much depends on attention to small points. In the first place it is very important that the surface of the plate glass should be very perfect, and scrupulously clean. To gain additional certainty of the film leaving the glass readily, treating its surface with wax, as we have often described, is desirable. It is important also that the collodion possess a good body, and be of the kind which gives a tough, horny film, and not a powdery film. By attention to these points you will probably succeed without difficulty.

**AN AMATEUR.**—We do not remember the focus of the lens in question, and cannot, therefore, tell you what distance would be required in producing a card portrait with it—probably about twenty-six feet. We should scarcely think it a lens well suited for card portraiture. If you address a line to the manufacturer, he will probably tell you the precise distance required.

**J. YELNATZ.**—You will find an article on the subject by the gentleman in question in the YEAR-BOOK for 1873. If you will describe the form and proportions of your present studio, we can probably give you some suggestions. It should not be a difficult thing with a good lens to secure portraits in a summer light with ten or fifteen seconds' exposure.

**W. G.**—Your negatives are certainly in a sad mess. The defects may arise from various causes. Some seem to proceed from the use of dirty plates, from which old negatives have been imperfectly cleaned. Others seem to proceed from the use of a newly-iodized collodion, with insufficient bromide to permit cleanly working whilst new. One negative seems chiefly to suffer from pinholes arising from an over-iodized bath. As you do not send any particulars of the mode in which your bath and other solutions are prepared, nor any specific history of your troubles, we can only advise you generally. Letters sent some weeks ago are not preserved, and we cannot, of course, remember from time to time the precise troubles of many scores of correspondents. Read article in present number on winter photography; and when you write again, give us fuller particulars of your operations, and of when and how your troubles arise.

**LORD RAYLEIGH.**—Many thanks. We shall have pleasure in shortly testing the grating you are good enough to forward, and which was duly received.

**E. SMITH.**—It is difficult, without having a precise statement, to suggest at what point they are wrong, but it is clear that they are so somewhere. The portion of your gelatine film which should be insoluble appear to be soluble, absorbing water and repelling greasy ink; and the portions which should do this appear to be insoluble, and take greasy ink, giving a reverse image, and that of a very imperfect kind. If you describe your operations in detail, we may possibly aid you by a suggestion. There is no work on the subject, and almost every operator's practical knowledge is gained by personal experience in working out published formulae.

**M. T. R.**—Imperfect fixation. During frosty or cold weather it is wise to slightly warm the fixing bath. In making a fixing bath you may notice that as the hyposulphite dissolves there is a great fall in the temperature of the solution, which becomes much colder than the water used in making it. Use hot water for preparing the bath, and immerse the prints in the solution while still slightly warm. There is great risk of imperfect fixation when the solution is very cold.

**R. G.**—It is one of the defects of the method of intensifying by means of mercury that it often leaves the film so porous that the varnish makes it nearly transparent. Much depends on the character of the image as to whether it can be intensified after varnishing. If the film be white or grey, the result of treatment with bichloride of mercury alone, without iodide or sulphide afterwards, then first moistening the film with alcohol and applying a weak alcoholic solution of iodine will convert the image into a yellow one, which will give it printing value. It is possible, also, to wash the varnish partially or totally away with alcohol, and intensify with alcoholic solutions of pyro and silver, which take better under the circumstances than aqueous solutions.

**B. F.**—A good quarter-plate lens will answer very well for enlarging from card size up to twelve by ten. We should recommend you to try the enlarged negative principle.

**A. M. C.**—We have described modes of vignetting in the camera several times. A simple method consists in making a screen of cardboard (say twenty inches by fourteen) with an oval aperture six or eight inches long, with serrated edges. This placed at a suitable distance in front of the lens will vignette the figure, and give the irregular edges of the oval aperture sufficiently out of focus to produce a vignetted effect. A light grey background should be used, and the screen may be of a light grey or white. If the screen be moved a little during exposure, the result is better still. The result is a vignetted negative which prints vignettes without trouble. This method deserves more attention than it has received.

**N. T.**—So far as we are aware, Jacoby's printing frame has not been introduced into this country; but it should not be difficult to make a frame for a similar purpose.

**BICHROMATE.**—In referring to any formula which has appeared in our pages you should give a specific reference. Captain Waterhouse has contributed many articles on the subject, and we cannot refer without knowing to which you allude. So far as we can see, adding the bichromate to the solution would answer as well as soaking the film, although it is probable that Captain Waterhouse has some good reason for recommending the latter course. The gelatine film, after exposure, is to be washed with cold water, using two or three changes. No specific length of time for washing can be given; but you will know when the last washing water has no trace of yellow that all the free bichromate has been washed out of the film.

**LUX.**—Difference of opinion prevails as to whether there is some specific accelerating value in coloured light, or whether it merely serves as giving a regulated amount of diffused white light, some white light being generally mixed with coloured light. Various plans of obtaining a small amount of white light under strict control have been tried. A very simple one consists in exposing the plate in the camera for a few seconds to a dark background before exposing it on the sitter.

Several Reviews and other Articles in type are compelled to stand over.

Several Correspondents in our next.

## The Photographic News, January 16, 1874.

### THE BEST WAY TO MAKE ENLARGEMENTS.

BY B. J. EDWARDS.\*

In opening the discussion this evening, I propose to say very few words on the subject of "direct pictures *versus* enlargements." The arguments in favour of enlarging from small negatives have been so ably stated by Mr. Croughton, in his paper read to you at the last meeting, that I have little to add, except to call your attention to one important advantage in favour of enlargements which Mr. Croughton has entirely overlooked. I allude to the power of securing at will that diffusion of focus so essential in a large picture. It is well known that owing to optical difficulties it is impossible to produce large direct portraits with anything approaching perfect diffusion of focus in the various parts of the picture, notwithstanding all that has been done by our best opticians in getting rid of the painful sharpness in one plane caused by over-correction in large lenses. A large portrait taken direct in the camera must always, in the nature of things, be considerably out of focus in some more or less important parts of the picture. By adopting the plan of enlarging, no such difficulty exists; provided the original negative be tolerably well defined, any amount of diffusion can be readily obtained at the will of the operator. I shall have the pleasure of showing you some examples of this in the negatives I have brought for your inspection.

With regard to the best way of making enlargements, this is a matter to which, as you are aware, I have devoted a good deal of study and attention. I think I may claim a large share in forcing the subject upon the notice of photographers, having been, perhaps, the first to demonstrate before the members of this Society that enlarged negatives could be made to produce prints equally as perfect as the originals. It is, however, with much diffidence that I offer any remarks this evening, inasmuch as my process is what is termed a "secret process." I have never myself so called it, and I think you will agree with me that as it is already in the hands of more than two hundred professional photographers in this country, it is hardly entitled to be termed a secret process. My desire is, that it should be still more widely known. I should like to have every intelligent photographer in the kingdom for a pupil and a subscriber. I have, however, no wish to make this Society the means of a trade advertisement. The fact that a member of our council, who is also professionally engaged in making enlargements, has so eloquently advocated his particular views as to the best way to make enlargements, must be my excuse for the few words I shall offer. While I cordially agree with Mr. Croughton on the many advantages of enlargements compared with direct large pictures, I must entirely differ from him as to the best means of producing the desired result.

Mr. Croughton, in his paper read at the last meeting, did me the honour to quote some observations of mine on a former occasion, in which I pointed out that he was in error in two important points in his method of working. He also, I understand, showed examples of his "double mistake." I have not had the pleasure of seeing those results, and must plead guilty to the charge of still holding the opinion that the method advocated by Mr. Croughton is wrong, both in theory and practice. First, with regard to the use of wet collodion for the immediate transparency, or positive cliché (I use the French term as being more expressive and appropriate), throwing aside the plea urged by Mr. Croughton "that it is so very convenient," I need only point out that for many years the ordinary wet process has been used for this purpose; it has been the rule, almost without exception; and yet it is only very recently that enlarged prints have been shown which will at all

bear comparison as untouched photographs with the prints from the original negatives, and in every instance where the untouched enlargement is as perfect as the small print, I will venture to assert that the positive cliché, no matter what process was used in its production, was not made on wet collodion. Why this is I shall not now take up your time in discussing. I have a theory on the subject which I may at some future time indite upon you; at present I will simply state, as the result of my experience, that in order to produce the best results, the transparency or positive cliché should be so perfect in texture that no human hand, not even the skilful fingers of a professional retoucher, can hope to mend or patch its exquisite gradation.

Mistake No. 2 consists, as I have said, in retouching an enlargement when the work required can be done better and quicker on the small negative. This subject of retouching is a difficult and much-vexed question; it seems impossible to determine how much or how little is a fair and legitimate part of the photographer's business. My maxim is, do no more than is absolutely necessary. We should all be glad to do without the retouching pencil altogether, and produce absolutely perfect negatives direct in the camera; but, as Mr. Croughton plaintively observes, "people will have freckles and blotches," and they must be got rid of by some means. But how? Mr. Croughton's advice is, first make your freckles and blotches from four to sixteen times larger, and then proceed to fill in or touch them out in the enlarged transparency. On the same principle, I suppose, a tailor, in order to mend a rent in a coat, ought previously to make the hole sixteen times as big, and then proceed to mend or patch it. I confess I cannot understand what advantage would be gained, unless the object be to show the patch. There is yet another reason why retouching should not be done on the positive transparency. It is well known that freckles and blotches, owing to their non-actinic colour, invariably photograph darker than in nature. How this can be remedied by adding more colour or black-lead without degrading the other and purer parts of the picture I must leave to Mr. Croughton to explain.

One word more on the subject of retouching. A curious misconception seems to have arisen as to the amount of retouching used in the pictures I had the honour of showing at the last Exhibition. I have this evening brought you a number of the large negatives, that you may judge of the amount of labour expended in this direction. I have also brought untouched proofs from the same. You will notice that, with one or two exceptions, the negatives are almost untouched. The enlargements being made from ordinary card negatives used for silver printing, and not made specially for enlarging, any good printing negative will make a good enlargement; the peculiar effect of fine finish which appears to have deceived other good judges besides our friend Mr. Croughton being due to the nature of the transparency and the method of producing the enlargements.

### THE PROGRESSIVE RESULTS OF THE PAST SESSION.

BY JOHN NICOL, PH.D.\*

I FEEL very much inclined to ask you to turn up to page 27 of last year's volume of the *British Journal*, and take what you will find stated there of 1872 as equally applicable to the year just closed. So little real progress has been made, either in the theory or practice of photography, that I really think this paper should have remained unwritten. I suppose, however, that there is in the Edinburgh Photographic, as in many other societies, a certain degree of conservatism which is unwilling to allow any time-honoured habit to pass away, even when the causes which brought it

\* Read before the South London Photographic Society.

\* Read before the Edinburgh Photographic Society.

into existence have long ceased to be; and, recognising the duty of obedience to those in authority, I consider the request of our secretary equal to a command, which I hasten to obey.

Collodio-bromide has, as usual, occupied a large share of attention, but little that is new has been brought to light. The necessity of a suitable pyroxylic has become more generally believed, and the conditions necessary for its preparation are better understood. Probably the greatest step in advance has been the introduction, by Col. Stuart Wortley, of his strong alkaline developer. It passed off, as most good things do, at first with comparatively little notice; but gradually it began to find favour, and, if I should think, now adopted by all emulsion workers, and, if I may judge from my own experience, those who give it a fair trial are not likely to give it up.

Mr. Sutton has written, with a zeal worthy of a better cause, in favour of his moist bromide process. Since its introduction he has hardly allowed a number of the *British Journal* to pass without some allusion to it, and I really was glad when I read his letter of December 12th, in which he promises to "drop the subject." If we are not able to progress, don't let us retrograde—as we should certainly do if we return to the moist messes of a bygone period; but of that I have little fear, as I do not think that any man who has mastered dry-plate work, and who can produce the exquisite results that it certainly can be made to give, will ever think of messing with a moist film.

How many photographers continue to lose their tempers and their time over fogged plates, by trying to develop in a light that contains too much actinism! And how often do we hear the question, "What kind of glass is best suited for the dark-room window"? If those unfortunates would only read the short letter of twenty-three lines, written by P. Le Neve Foster in the *British Journal* of January 10th, 1873,\* and invest a few pence in a very common prism, their troubles would vanish like mist in sunshine.

The question of shortening sittings by primary or secondary exposure under coloured glass, continued during the early part of the year to attract some attention, but I don't think Mr. Newton has made many converts.

My own experiments seem to show clearly enough that the only benefit derived from such exposure is the slightly fogging of the shadows, which prevents an under-exposed negative from printing so intensely white and black as it would otherwise do. This of course is a real gain, but it is better to attribute it to the proper cause.

The introduction of gelatine as a substitute for collodion in the emulsion process is deserving of particular notice. Although no really workable process has been published, there is no doubt that it contains all the elements of success, and I have no doubt that before the year is ended it will take a high place amongst dry processes. I would, however, direct special attention to Mr. Sutton's suggestion to make sheets of sensitive gelatine bromide tissue. This is, I think, not only practicable, but likely to become of the most valuable suggestions that has been made since Archer hit on collodion. I hope all who have time will turn their attention in this direction, and that before the season for field work comes round, such tissue will be a recognised article of commerce. If I were disposed to don the prophetic mantle, it would be to say, that if I am spared to write the "progressive results" of 1874, I shall have the pleasure of showing that the problem of instantaneous photography has been solved by the happy union of Sutton's sensitive tissue and Wortley's strong alkaline developer.

I am sorry to say that the question of how to make permanent sensitized paper is not yet solved. There are now several makers in the field, but they keep their methods to themselves. The subject is surely worth the attention of experimenters, and cannot be so difficult as to deter them from the investigation. I wonder whether, if the various

photographic societies throughout the country were to join in offering a suitable medal to the discoverer, we should get the desired information, and think it is worth a trial.

In carbon printing there has been nothing of importance new; but a large increase in quantity, considerably improved in quality has been done by the now well-known methods, and there can be little doubt but that ultimately silver printing must go to the wall. In connection with this matter, mention may be made of the two processes introduced by the late M. Marion, in the middle of last year. They seem, however, to have been unworkable, or at least to have died with their inventor.

This review would hardly be complete without including a word or two about the Crawshay prizes for large heads. The exhibition of prize pictures gave rise to a little ill-feeling, and a good deal of stupid writing, but, on the whole, it must have an influence for good. Direct large pictures are worthy of more attention than they have yet got, and I have no doubt that next exhibition will show much improvement in quality, and I hope also in quantity. If, however, the competing pictures are to form part of the Photographic Society's Exhibition, I would strongly recommend the council to consider whether it would not be advisable to limit each exhibitor to three specimens; too much of even a good thing is never good.

And now, in conclusion, let me bear a humble protest against what I cannot help calling a desecration of our art in high places. I allude to the widely published information that the Shah, while residing as our own guest, in one of our royal palaces, found a photographer who, instead of obeying the good old injunction to "remember the Sabbath day," did not disdain to take rank amongst those Pariahs of our art, who by their unblushing open desecration of the Sabbath, do their best, or rather their worst, to bring disgrace on a noble profession.

#### PROCESS FOR PRINTING ON WOOD OR CANVAS.

BY T. C. ROCHE.\*

The following formula will be found useful to wood engravers, or to those who are photographing on wood. To prepare the block for the sensitive coating, make a thin solution of gelatine, six grains to the ounce of water, mixed with some gilders' white; coat the surface of the block with this, using a wide camel's-hair brush; when dry, brush over the prepared surface in the dark room some of the following solution:—

1.—Red prussiate of potash	...	120 grains
Water	...	2 ounces
2.—Ammonia-citrate of iron	...	140 grains
Water	...	2 ounces.

When dissolved, mix together and filter. This solution should be kept in the dark. When the coating has dried, expose under a negative in sunshine for ten or twelve minutes, then take the block where the light is not very strong, and wash the surface lightly with a soft sponge in water, and a beautiful dark blue picture will appear that will not chip in cutting.

To make a red picture, prepare as above, but use the following mixture:—Dissolve twenty or thirty grains of sulphate of uranium in one ounce of thin gun-arabic or gelatine water; brush this on the block or canvas in the dark room; when dry, expose under a negative for ten to twenty minutes in sunshine, then wash well with a sponge and water; now take a clean sponge charged with a solution of red prussiate of potash, twenty grains to the ounce of water, and apply it quickly all over the surface, and the picture will appear immediately. When all details are out, wash clean with a fresh sponge and water. A drop or two of muriatic acid in some water will bleach the picture if over-printed.

\* The readers of the PHOTOGRAPHIC NEWS were familiar with this years ago.

## A NEW TEST FOR HYPOSULPHITE OF SODA.

BY W. H. SHERMAN.\*

FIRST prepare the following solution:—

Bichloride of mercury ...	1 ounce
Chloride of ammonium ...	175 grains
Water ...	8 fluid ounces.

Dissolve, and add one fluid drachm pure hydrochloric acid.

Now perform the following experiment. Into a test-tube that will hold five or six fluid drachms drop a single drop of a ten per cent. solution of hyposulphite of sodium. Fill the tube with water, shake well, pour out the water, and let drip until none of the liquid remains excepting what adheres to the glass; again add one or two drachms of water, shaking as before; to this add a few drops of the mercurial solution, and observe the change of colour which will take place. A slight blue colour or opalescence will make its appearance, due to the minute quantity of hyposulphite remaining after the rising above described. Evidently the quantity is very small, and the test must be conducted with nicety. The glass must be scrupulously clean, and the water clear. It is also well to practise the eye by holding another similar vessel containing only clear water beside the one under inspection. One curious in such matters will be tempted to try other experiments. Presuming that the change in the colour of the liquid is owing to the formation of the hyposulphite of mercury, he will be quite apt to try the corrosive sublimate alone. This he would find to be less sensitive. The addition of the sal-ammoniac forms the mercuric double salt  $\text{HgCl}_2 \cdot 2\text{H}_2\text{NCl}$ , and the hyposulphite converts the mercury into the sulphide.

But what is the use of the hydrochloric acid? Answer: If the water used in the experiment happened to contain carbonates (hard water), carbonate of mercury would be formed, and this would produce turbidity similar to the hyposulphite. The acid prevents the formation of the carbonate mentioned, but does not interfere with the formation of the mercuric sulphide.

Having prepared the test solution as above prescribed, and having become accustomed to its most delicate indications, proceed to apply it to practical use in detecting the presence of hyposulphite in the prints as the work of washing progresses. It will be interesting to note the persistence with which this pernicious but indispensable salt maintains its presence in the paper. After washing the prints, until the water shows no signs of a remaining trace, place a few strips of the paper in a little water, and subject to a gentle heat. This trouble will be repaid by its again manifesting itself to the test.

The less of the hyposulphite left in the prints the longer they will last. In practice it is never completely removed by washing. The remaining portion is the remote cause of fading. Sooner or later sulphur is liberated, producing the characteristic yellow colour. Oxidation of the sulphur produces an acid, which becomes the immediate cause of fading. Every time the hyposulphite is used another unstable substance is added to the solution, to wit, hyposulphite of silver. This being less stable than the hyposulphite of sodium, the longer this bath is used the worse it becomes. In consequence, the land is filled with fading photographs to the disgrace of the art.

## HOW TO BUY A LENS.

BY W. J. BAKER.\*

WE fully subscribe to the almost axiomatic proposition that "the best is the cheapest;" the cheapest either to buy or to sell, and especially the cheapest when it comes to a matter of so vital importance as a lens.

Some time ago we had occasion to test some lenses for a friend and for ourselves, both small and large sizes, and resolved to have the cheapest at all hazards, even if it cost half or twice the money. The tests applied were comparative and practical, and in our own case served to eliminate doubts that had been raised by the conflicting claims of "first-class" makers.

We give below a resumé of these tests, and any who choose to apply the same, or similar ones, will no doubt arrive at conclusions which, if not the same as ours, will be satisfactory and convincing, and enable them to purchase with a clear understanding.

It will only be necessary to describe the trials of the larger lenses, as the same method was applied to the smaller ones, and with the same result.

We started with no fixed ideal which the performance of the instruments was to equal. We did not expect a mammoth to "cut" in the same proportion as a  $\frac{2}{3}$  or 2B. Knowing something of the rapidly increasing ratio of imperfections that have to be equalized and corrected,\* we resolved to be contented with the best that leading opticians offered; and here we will say that, as far as we can, we shall refrain from indicating who the makers were, as this is not the part of the book in which advertisements are legitimate. Look for those near the covers, read them, and then find out for yourselves how much or little truth there is in them.

The lenses will be designated as A and B. A was made to order, subject to approval. B was one of a number of the same size ready made.

Test first, of price. A cost over fifty per cent. more than B.

Test second, for whiteness of glass. The lenses were unscrewed and placed side by side on white paper. B proved to be of much clearer, whiter glass than A, which had a rather yellowish-green tint.

Test third, for comparative ratio of aperture to focal length. B was by measure a fraction of an inch larger in diameter than A. The focal lengths were obtained by measuring the distances of the image from the object (dots twelve inches apart on white card); the image was in each case made the same size as the object when focussed with the full opening. Had a small diaphragm been used there might have been an error, as in this case there is some latitude in focussing. The distances when quartered gave pretty nearly the equivalent solar foci. B had a somewhat longer focus than A, but in each case there was about the same ratio between the squares of the apertures and the focal lengths respectively, from which it might be expected that they would work in nearly equal times, while the superior whiteness of B would be an element in its favour.

Test fourth, for actual times of working. This test was very carefully conducted, repeated several times on different days, always about noon, with a clear sky. A still subject in half-tone was used, and care taken to distinguish between an increase of intensity, which might make the detail in the shadows more apparent, and actual amount of detail obtained with similar and dissimilar exposures. These trials showed that A, with forty seconds, equalled B with forty-five seconds, a difference of but little practical value.

Test fifth, for definition, made by copying an engraved head of four inches length to the same size with full apertures. Very decided in favour of B.

Test sixth, for flatness of field, made by copying a newspaper to actual size, and by pushing in the ground glass till the centre letters were barely sharp. Much in favour of B, which had a field of sharp letters almost double the linear extent of A, though it was surprising how small the extent of apparently flat, well-defined field was in either

\* *Photographic Mosaics.*

\* The spherical aberration increases as the square of the aperture, the chromatic as the cube.

case. When, afterwards, the lenses were tried on standing figures, the comparison had the same result.

Test seventh, for marginal definition, conducted with the newspaper as above, by focussing as sharply as possible the letters that came on the outside of the field. A was nowhere with B in this test.

Test eighth, for depth. This we have always, by theory, held to be a quality decided, other things being equal, by the ratio of the aperture to the focal length, and these trials only convinced us of the correctness of that opinion, as there was no perceptible difference. A finely engraved card was focussed, and then slid to and from the lens on a line, as nearly as practicable, coincident with the optical axis of the lens.

The above seemed to include all the important qualities of portrait lenses valuable in practice, and, to recapitulate, gave tests first, fourth, fifth, sixth, and seventh in favour of B; tests third and eighth neutral; test fourth in favour of A, so slightly that we formed in our mind the conviction that while the "best is the cheapest," the highest priced is not always so.

### PORCELAIN PRINTING WITH COLLODIO-CHLORIDE.

BY CHARLES W. HEARN (YOUNG PRINTER).\*

In preparing for porcelain printing see that you obtain good flat plates, which are totally free of any roughness that will eventually spoil the looks of the finished porcelain print. Great care should be exercised in this primary operation, as the result depends in a great measure upon it. If any plates should be curved, but otherwise good, use the convex side for flowing the collodion on, and then perfect contact will be insured between the negatives and porcelains. The cleaning of the plates can be done very nicely by any of the usual methods now in vogue, such as to first immerse them for a day or two in a strong solution of concentrated lye, and then afterwards in a solution of nitric acid one ounce, and water six ounces. Only varnished plates need to be placed in the lye solution, acid and water being all that is required for new ones.

*Albumenizing Solution.*—Take the whites of perfectly fresh eggs, and beat to a stiff froth, let stand over night, decant, and to every ounce of albumen add five ounces of pure filtered rain or distilled water and enough liquor ammonia to give the solution a slight smell of the vapour. Filter with great care; and when a porcelain plate is thoroughly rinsed of the acid water, and well drained, pour a little of this filtered solution on; and after draining in the sink, flow again, and let the plate dry spontaneously, and away from the least draught of air.

*Porcelain Collodion.*—A. Plain Collodion. Alcohol, seven ounces; ether, nine ounces; gun-cotton, seven and a-half grains per ounce.

B. Crystallized nitrate of silver, one ounce; distilled water, one ounce.

C. Chloride of calcium, thirty-two grains; alcohol (95 per cent.), one ounce.

D. Citric acid, thirty-two grains; alcohol (ninety-five per cent.), one ounce. Mix exactly in the manner described below.

Take four ounces of A (plain collodion), decant carefully in an eight or ten-ounce bottle; now add thirty-two drops of B (silver solution) to the plain collodion, adding to or three drops at a time, and shaking well between each addition; now add, more carefully still, about a quarter of an ounce of C, adding one, two, or three drops at a time, also shaking well between each addition as above; add in the same manner a quarter of an ounce of D. This collodio-

chloride is very reliable, and after it has been standing a few days it will work beautifully, indeed it has done so in an hour or two. Flow the plate carefully, let set, and place it in the fuming-box, and fume with strong aqua ammonia three minutes; dry by gentle heat, and after cooling gradually it will be ready for printing purposes.

The Lochman's porcelain printing-frames are undoubtedly the best that has ever been introduced, on account of its superior advantages, although the Chapman's frame are very good, and perhaps more in use than the former. Print considerably darker than you would do to a paper print, and before washing the plate flow back and forth over the plate a solution of common alcohol, until the print has red up to a beautiful color, which it would do in a very few minutes. Wash well under a gentle stream of water, until the free nitrate has washed off, which can be easily ascertained by tasting the drops that fall from the plate. Do not wash too long.

*Toning.*—Take fifteen grains of Wing's chloride of gold, and add fifteen ounces of pure distilled water, and label "Stock Gold Solution." Take of this stock about a dozen or fifteen drops, and make alkaline (slightly) with bicarbonate of soda, and then add about five ounces of water to the whole; let stand in the light for about fifteen minutes, and then tone in a quite weak light, and until the face of the porcelain print looks clear and slightly blue, even if the draperies are quite red, for the porcelain is toned when the face is blue. Unless you have had considerable practice in toning by hand you had better tone the porcelain in a shallow dish.

*Fixing.*—Saturated solution of hyposulphite soda, one ounce; water, ten ounces. Fix ten minutes, by which time the face has returned to the tone you toned it, and then it is a success if there has been no mistaken calculation as regards depth of printing, &c. Wash thoroughly in changing water for about two or three hours; dry and tint with dry colours, the least trifle more than what you wish it when finished, for in varnishing a little of the colour disappears; when there is simply tinting of cheeks and lips to be done, I prefer to do it by dry rather than by water colours. The colours can be put on after varnishing if desired.

*Varnishing.*—When you are ready for varnishing the plate, warm it slightly, and varnish it with a filtered solution of pure white shellac varnish, and it will give you as firm and glossy a surface as you can desire.

The above is my method of making porcelains, and which I find very successful in the majority of cases. The only great failures in porcelain making are, first, the collodion is not good; and second, they are not toned properly. Do not expect to obtain the very best results with porcelain collodion just made up, especially if carelessly so, and with the exercise of poor judgment in printing and toning.

In making porcelains, do not be discouraged, but strive to overcome all difficulties, for ultimate success will more than repay you for your trouble. Remember, "If you don't at first succeed, try, try again."

### NOTES ON PHOTOGRAPHY IN THE ARCTIC REGIONS.

BY LIEUT. CHERMSIDE, R.E.\*

We next set to work to discover our causes of failure; and as a history of our gradual progress would only be wearisome, I will merely inform you of the results as regards the bath and other solutions when I treat of each separately further on. On the 12th, after a hard day's work on the ship and from the shore, in our passage to which we had often to haul the boat over ice, we had so far advanced as, after failure, from the ship's motion, in getting any but blurred images,

\* *Photographic Mosaics.*

\* Continued from page 16.

to take an instantaneous photograph, or, as I know that term is incorrect, one with as short exposure as we could give. The film of this subsequently came to grief; but the portion of it left uninjured has given a print which I have here to-night. Our next few negatives were ruined through our losing the films by their cracking in this way, either in washing or drying. When this difficulty was overcome, there only remained to varnish the negatives: this for a time puzzled us, as we almost invariably got a matt surface, for which we could not account; and when we had succeeded in varnishing with a clear surface, until new difficulties with our bath commenced, we had attained the partial success which enabled us to bring back the negatives that we have; and faulty though they doubtless are, I do not think any defect but that of stains from the bath solution running back over the film is attributable to the conditions of photography in the Arctic regions. When it is remembered that you often may have to swing down a hanging rope ladder from the bowsprit with your slide; to place it flat on the snow, on account of the wind, while you shift the camera; to row in a boat against a stiffish sea, placing it wherever safest; to drag the said boat, slide, and all out of the water, and over ice, to hand back the slide up the ship's side, it is hardly to be wondered at that it is sometimes almost impossible to keep the plate continually in the same position it is in the camera; and when one of these compound journeys must be undertaken, the best way seems to be to protect the plate as much as possible with blotting paper, and, wrapping up the slide in a focussing cloth, to let it take its chance.

Indeed, it is often the best and quickest way for one to remain on board developing and preparing plates, and sending them off by some of the sailors, while another of the party sets up the camera and exposes the plates as he receives them. The sailors used to take a great interest in our proceedings, and to carry the "camera," as it was called, with great reverence; the slide, too, as containing the picture, was an object of great curiosity, and when entrusted to their care to be taken back, the appearance of the negative more than once proved that they had taken a peep at it during carriage. I have here a print from a negative so treated; but a horizontal dark band across the sky was luckily the only injury it received.

I will now proceed to consider more in detail the various difficulties we at first experienced, and the remedies adopted.

It seemed evident from our first day's work that our failure was not in any great degree attributable to our bath or collodion, as the plate on removal from the bath was covered with an even opaque film, although, possibly, from the low temperature of the bath, the bromide of silver was not completely formed. This might, of course, injure the sensitiveness of the film. Our failure must therefore, we concluded, be in our developing solutions; and we considered that this was owing to two causes—namely, the low temperature at which they had been prepared and kept, and the water used in making them up.

This water was from the ship's tanks, and, though twice filtered, from the recent lime-whiting of the tanks it still contained large quantities of lime and other impurities; and those present in the developer, when poured over the film, formed with the free nitrate of silver upon it flocculent precipitates of carbonate and chloride of silver.

Water was next boiled and filtered, and we managed to rig a large earthenware filter, which proved of the greatest use. Where distilled water was required we used water from the condenser in the engine-room; and when filtered to remove greasy matter this served our purposes well enough. The only remaining difficulty with water was one we never quite got over—that is, to prevent its splitting the films in washing; but applying it at a temperature of from 60° to 70° Fah. greatly modified this danger. I will now describe, in each of the processes necessary for the production of a negative, the peculiarities that struck us.

First, as to cleaning plates. I should advise any one likely to practise photography in high latitudes to take a large supply of clean plates covered with albumen, as they will then be always ready; whereas plates cleaned in the ordinary way will not keep clean up there for more than a few hours. It was almost impossible to get a plate satisfactorily cleaned—at least, to get the moisture to fly off it as it should—even with the use of a stove, as when it had been allowed to cool, from the great difference of temperature, the breath readily condensed on it again. The lenses are also particularly liable to become clouded over, and it is often necessary to unscrew them and wipe and clean them on both sides immediately before taking each photograph. After continued rubbing, the plates remain for a long time electrified, attracting light substances for some minutes, and when coated in this state, or at all hot, seem to exercise a repellent action on the film of collodion.

The collodion used was Thomas's bromo-iodized, and this worked well all through; and the difficulty of preventing films splitting in washing after fixing, and in drying, was equally observable with two other collodions that we tried.

This could not, I think, be owing to excess of ether, as we for some time kept a bottle containing collodion unstoppered at a temperature above 45° Fah., and added alcohol to it, and also, as density was our desideratum, a considerable amount of iodizing solution was added in order to overpower the bromide, but with little effect. We could, indeed, easily afford to sacrifice some of the extreme sensitiveness we found existing in the films for increased density, and, probably, had we had any pyroxyline to add to our collodion, we should have obtained the desired result. A specially prepared collodion, manufactured with pyroxyline and papyroxyline rather in excess of the usual quantities, would doubtless give the required density and toughness of film. I have, moreover, little doubt that it would be worth while, in high latitudes, to use for many subjects a simple iodized collodion with an iron developer.

I now come to the sensitizing bath. We used Thomas's bath solution, made up by Thomas, and as soon as we found the necessity of an even temperature it worked well. It was never permitted to freeze, being kept continually in a warm place; notwithstanding which it became rapidly impregnated with ether and alcohol. It was then heated and filtered; it could not be boiled, owing to the want of a vessel for the purpose. This operation had often to be repeated, and this filtration at any rate counteracted the effects of over-iodizing. When alkalinity occurred, fresh solution was substituted, as unfortunately we had no nitric acid with us. When, however, all the solution had been used, we were perforce obliged to commence doctoring and experimenting. Crystals of nitrate of silver were added without success, and then a weak solution of cyanide of potassium was tried; next acetic acid, which at once formed acetate of silver, and made matters worse than ever; we then experimented with all the acids we could find in the medicine-chest—citric, tartaric, &c.—but as none succeeded, it is not worth while describing their effects.

For the remainder of the time we used the bath solution in a shallow dish, rejecting it as soon as it got out of order; and this, I imagine, from the great absorption of ether and alcohol that takes place from the effect of the climate, would prove the most satisfactory, as well as economical, method. From five to eight minutes was the time adopted for immersion in the bath, except when plates were sensitized a long time prior to development, when they were removed as soon as all greasiness disappeared, and would then keep for over an hour. Indeed, in those regions wet plates will keep a very long time without injury.

(To be continued.)

## THE PHOTOGRAPHIC SOCIETY.

It was a somewhat unusual sight for the members of the Photographic Society to see, as they did on Tuesday evening last, any of its members in antagonism with the Chairman, and not less unusual for a series of counter-nomination lists handed in, proposing members of council for election at the annual meeting to be held next month, the house-list issued by the Council having been accepted without opposition for many years past. It was almost a pity that a jarring chord was struck at the outset on a petty formality as to the record of minutes, as it tended to give a tone to subsequent proceedings by no means necessarily belonging to them. The presentation of members' nomination lists proposing other candidates for vacancies in the council is an act as simple and as legal as that of the council in putting forth their list at the previous meeting, is thoroughly provided for in the rules, and is, indeed, the only method of securing the carrying out of the first provision in the law relating to the election of officers, which is directed to be conducted by ballot, and without competing lists it is clear that there can be no ballot. It is clearly open to any member to object to inaccuracy or incompleteness in the minutes; but it was obviously inexpedient that a gentleman who was not present at the meeting, and therefore only knew of its proceedings by hearsay, should have undertaken the office of correcting the minutes. That Mr. Stillman was quite single-minded and free from anything like *malus animus* in his objection, we are quite satisfied; but the fact that he could not speak from personal knowledge, and that he tendered the report of what the Chairman styled a "commercial journal" as evidence, was most unfortunate, as it compelled the Chairman to decline his correction, and to refuse the report as evidence against the minutes of the Society. The reports in commercial journals, we will venture to affirm—and we feel assured that our remark would be endorsed by the President—are generally both interesting and accurate, and it is to the interest of photographers that they are independent rather than official. But this fact disqualified any journal from being presented as evidence from a gentleman who knew nothing from personal knowledge of its accuracy. Further, it should be remembered, in any case, that a report of proceedings in a journal is a much fuller, as well as a less formal, record of proceedings than "minutes" can by any possibility be expected to present, and the absence of something from the latter found in the former is by no means an evidence of inaccuracy on either side. The matter was, however, easily set right by the courteous and temperate interposition of an explanation by Mr. Sawyer, as a member who was present, and the missing minute was supplied.

A stricter adhesion to the rule relating to nomination of officers would prevent the slightest approach to the appearance or expression of antagonism when counter-lists are presented. The rule provides that in the event of the list proposed by the Council in the December meeting not proving satisfactory to members, any one shall have the opportunity of proposing a fresh list at the January meeting, the ballot being taken at the annual meeting in February. The mode of nominating a fresh list is prescribed, a written list is to be delivered to the Secretary at or before the January meeting. This, strictly carried out, would obviate, as it is clearly intended to do, the invidiousness of any individual rising in a meeting to make such proposal, as well as the chance or necessity of discussion or antagonism. Personal nomination being thus rendered unnecessary, any member in town or country possesses the power and opportunity of proposing members of council by writing a letter to the Secretary in time for the January meeting. The names so proposed will then be read by the Chairman to the meeting. Speech-making or explanation is so rendered unnecessary; as the Chairman observed on Tuesday evening, every member being strictly within his right in making such nominations, is not called upon to give reasons for so doing. The practice here referred to has been so long in abeyance it seems probable that many members have scarcely understood their privileges and duties in the matter. As it is probable the rules will shortly undergo revision in relation to such elections, a perfect knowledge of the existing rules loses something of its importance now.

There is another point in connection with these nomination, not without interest. They include a number of able and estimable men, any one of whom will make an eligible council man. But it is noteworthy that every one of the lists retains some of those nominated by the council at the December meeting, one of them retaining all the names but two, and, as there are but seven elections to be made, it is apparent that no very serious divergence of opinion prevails between the council and their quasi opponents.

There are also one or two curious anomalies, in appearance at least, in some of the lists. In two of the lists we find several of the same names occur in each. In each we find the name Mr. J. R. Johnson nominated as Vice-President. A more fitting man for the position could not be found in the Society. Distinguished by great skill and origiative ability as a photographer, by large scientific culture, great intellectual power, and singular justness of character, he is every way qualified for the office. We also find in each of the lists the name of Mr. J. A. Spence proposed as a member of council. Mr. Spence is a gentleman in every way well qualified for the office. He is well and favourably known to most photographers, distinguished by unusual skill and excellence in more than one manufacturing branch of the art, a man of large experience and shrewdness, and unusually winning and urbane in bearing, and one of the best fitted on either list for the position of councilman. For each gentleman we have the highest personal esteem; but they are both connected with, and may be said to represent, the Autotype Company. This is certainly not an objection *per se*. We have always maintained that this Company is doing work which will stand amongst the most honourable monuments which the art can at this day claim. The existence of the Company is a boon and an honour to photography; but is it good policy, is it simply consistent that a party—for a party must be recognized as recent objectors to the council—complaining of *camaraderie* in the existing council, should propose two gentlemen connected with one firm as a means of securing independent action, free not only from *camaraderie*, but from the suspicion of such a thing? Further, the allusion of carbon printing necessarily recalls the name of Mr. Swan. One of the complaints made by some of those who have placed themselves at the head of the opposition movement was that the council had nominated Mr. Swan, who, as a

gentleman residing in the country, could not readily attend council meetings. Mr. Swan resides at Newcastle-on-Tyne, but is a frequent visitor to town. In order to preserve consistency, the objectors reject Mr. Swan for non-residence, and propose Mr. Elwell, of Weston-super-Mare! Mr. Elwell's very excellent work we well know, and we know him by correspondence as a cultivated gentleman, and shall hail his accession to the council, if he be elected, with much satisfaction; but we must admire the discrimination between the degree of non-residence, which affects the question, when a distinction is made between Newcastle-on-Tyne and Weston-super-Mare.

It was not a little curious, also, that as the rules make no provision for electing a president, two of the lists contained a nomination for president. The rule relating to the tenure of office states that one of the vice-presidents, five of the council, and the treasurer shall go out of office annually, subject to re-election. One gentleman, in referring to his nomination, justified himself by quoting the seventh rule, which commences, "All officers shall be annually elected," but he omitted to finish the sentence, which says, "with the exception" of those who do not "go out of office by rotation or otherwise." The President does not go out by rotation or otherwise. The office is for life, or until the holder shall resign. It was held so by Sir Charles Eastlake, it was held so by Chief Baron Pollock, and that gentleman pointed out that it was a life tenure to his successor, Mr. Glaisher. Whether such a system is wise is open to consideration. By its operation a society might be saddled with the permanent burden of an incompetent or disagreeable man. In the case of the Photographic Society it has worked well, because it has been fortunate in its presidents. Its present President has served it admirably, and possesses just the fitting qualifications for presiding. Position, experience, suavity, firmness, decision, and knowledge of the forms of public business. Continuance in office of a good president is, we believe, a great advantage to a society; fixity of office might become a great evil. Mr. Glaisher, we know well, would never maintain his tenure of office on the ground of technical right if it were opposed to the wish of the Society. He would prefer to hold his continuance on the ground of popular suffrage rather than more legal right. That continuity of office in the case of a suitable man is good cannot be doubted. The South London Society has had one President during the whole of its fifteen years of existence, and no greater calamity could occur than the resignation of Mr. Statham.

The Chairman felt it was a healthy symptom that so much interest was taken in the government of the Society, and, in degree, we believe he was right. Another gentleman remarked to us that in Parliamentary government nothing was more beneficial and healthy than an active opposition, and he, too, in degree, we think was right. Progression by antagonism is something more than a philosophical theory; and we have no doubt that the Society will, after casting some sloughs of clumsy laws, rise invigorated and more firmly established to promote the advancement of photography.

#### MODES OF PRODUCING LARGE PHOTOGRAPHS.

The debate on Mr. Croughton's paper at the South London Society, on the evening of Thursday week, although more restricted in its character than the scope of the paper and the interest of the subject rendered desirable, was not without interest. The object of Mr. Croughton's paper was to enforce the advantages of enlargement over direct large portraiture. The object of the paper read by Mr. Edwards on Thursday night was to affirm the inferiority of the method of enlarging advocated by Mr. Croughton, as compared with that of Mr. Edwards and similar methods. The question of producing large direct pictures was left out in the cold altogether, and, but for some interesting

passing allusion by Mr. Aldridge, would have been left entirely without notice.

The discussion was practically narrowed to the enquiry: Which is the best mode of producing the transparency from which to produce an enlarged negative? Mr. Croughton maintains that the method of producing a transparency on wet collodion in the camera, enlarged (say) to half the extent required in the finished enlargement, touching on this transparency before producing the enlarged negative, is the most easy method of producing fine results, especially where the original negative renders ameliorations necessary. Mr. Edwards, on the other hand, maintains that the transparency should be produced of the same size as the original, by contact printing on an albumen film, or something equally free from structure, and that no attempt at retouching the transparency should ever be made, as, if it have been properly produced, it is impossible to improve it by the pencil, or to touch it at all without injury. Whatever of retouching is necessary should be made, he contends, on the original small negative, retouching on the transparency being injurious, and on the enlarged negative rarely necessary. The strongest argument on Mr. Edwards' side is the importance of a structureless film for the transparency, and the importance of contact printing. The small negative produced by the wet process is, as a rule, more or less irregular in texture, the structure of the collodion and the granular character of the silver precipitated in development and intensifying combining to produce this result. When an enlarged transparency is produced from this negative the irregular structure is, affirms Mr. Edwards, enlarged in the same ratio as the image, and when this exaggerated structure and the structure of the film on which it is produced are again magnified in producing the enlarged negative, the result is, according to Mr. Edwards, inevitably coarse and displeasing. To avoid all this, Mr. Edwards insists that the irregular structure in the original negative must be translated into homogeneous or textureless film before any enlargement is attempted, and that this is done in contact printing upon an albumen film. To this Mr. Croughton's reply is twofold: he points to examples of his own work where none of the offensive qualities described are present, and he points out the ameliorating power he possesses in the mode he advocates. On the subject of ameliorating the transparency there is scarcely so much discrepancy between the practice of Mr. Croughton and Mr. Edwards as at first sight appears, and as each seemed to believe, as they both really do lay stress on such amelioration. Mr. Croughton effects his with pencil, and make his modifications as extensive as he pleases, whilst Mr. Edwards makes his modification only by printing through a medium to soften definition. If the retouching on the small negative be too crisply rendered, or if granulation, reticulation, or defective texture be too sharply reproduced on the transparency by perfect contact between the negative and dry plate, that contact must be broken, so as to soften the definition by making the lines of texture or retouching merge into each other.

In connection with this subject of contact printing Mr. Edwards advanced a theory which will be not a little startling to many photographers. In pointing out that ordinary printing on albumenized paper did not secure perfect contact between the negative and sensitive surface, he expressed a conviction that the print so produced was absolutely an improvement on the negative by reason of that imperfect contact. The surface of albumenized paper, consisting of a multitude of little prominences with spaces between, literally hills and valleys, and the hills only in contact with the negative, the print generally could never render all the sharpness the negatives possessed; and as it could not exhibit all the sharpness of definition, neither could it reproduce, in all their hard offensiveness, all the freckles, rugosities, and other microscopically rendered defects of texture often found in a sharp, brilliant negative.

That the albumenized print does not render all that is found in the negative has often been pointed out, and almost as often lamented, various devices having been suggested to secure a more perfect contact and more perfect rendering. Notably, it was recommended a few years ago to press the paper after sensitizing and drying, so as to secure a smoother surface. Various substances have been proposed as a substitute for albumen, chiefly with the view of obtaining a more perfect texture and surface. Nevertheless, we are disposed to regard Mr. Edwards' view as in a number of cases correct, and to believe that an absolute advantage is gained by the imperfect contact between sensitive surface and negative, a contact not sufficiently broken to destroy definition and produce fuzziness, not so close as to secure rendering of every minute trace of texture in the negative. It may, of course, be argued that the detail lost may be a loss of beauty, as easily as an escape from defect. That is scarcely probable, as neither the artistic beauty of the picture nor the truth of the likeness depends upon such microscopic renderings, and the strongly pronounced rendering of every freckle and wrinkle must inevitably be offensive. The artist can produce every gradation of light and shade, detail sufficiently minute for all purposes of pictorial truth, with a blunt crayon, and without the aid of a crow-quill pen. We have a strong conviction that for large portraiture the texture of rough drawing paper would often be more effective than a perfectly smooth surface.

To return, however, to modes of enlargement. We think that there are advantages in each of the methods under discussion which were scarcely acknowledged by its opponents. Mr. Edwards believed that Mr. Croughton's method was in every way wrong. He believed that working either on an enlarged transparency or an enlarged negative was an error when the work could be done easier and quicker on the original small negative, and was merry over the notion of a tailor making a rent in a garment many times as big in order to mend it the more perfectly. That, by the way, is neither so odd nor so unusual, as repairing is often effected on that principle. But he further mentioned that the transparency should be so perfect in texture that no hand of man could hope to mend its exquisite gradation. Now, when this magnificent transparency has been obtained, it is tolerably certain that no one will attempt to retouch it. To obtain such a transparency, however, perfection in the negative is necessary, which, it is unnecessary to say, is not always found when enlargement is necessary. Given a good negative skilfully retouched when necessary, and we think there is no doubt that nothing can exceed the plan advocated by Mr. Edwards. The minute traces of structure and granularity in the original negative are not of moment, inasmuch as, being invisible to the eye, they will practically cease to exist when the image is "translated," as Mr. Edwards phrased it, into the absolutely structureless transparency, and the enlarged negative produced therefrom will also be free from structure, and the result very perfect.

But, as Mr. Croughton very pertinently remarked, when good enlargements were required from imperfect negatives very different conditions prevailed. After the retoucher has done his best on the negative there may remain many defects. On the negative he can only add light: he can increase existing lights, he can strengthen weak detail, and soften black shadows, dark lines, and dark freckles; but he cannot add shadow, nor increase the depth of dark portions. If the negative be fogged or badly lighted, he cannot add a single dark touch. The eye-brows, eye-lashes, the pupil of the eye, often want strengthening; draperies, locks of air, often require a few sharp, deep touches; the background may require shade; in short, the whole range of improvements which, in a monochrome print, would consist of strengthening dark portions by touches with Indian ink and gum, most important elements in the force and brilliancy of a print, cannot be effected by touching the negative, and can be effected by working on the trans-

parency. And as the hand of man cannot readily assimilate its touches to the minute gradation in the small picture, the transparency is made larger to accommodate the human eye, human hand, and comparatively rough tools he must use, and so the better enable him to harmonize his work with that of the sun. In effect, Mr. Edwards recommends making the defect larger, that he may the better repair it, when he recommends the use of a larger magnifier in retouching. He makes it larger, at least to the eye, and trusts to the skilled hand being able to assimilate its work with that of the sun. Mr. Croughton prefers to enlarge so as to make the work easy for the hand as well as the eye; and he lays stress on the fact that every touch on the transparency has the same effect to the eye as a touch on the final print, so that, practically, the picture is before him, and his work, unlike that of touching the negative, is direct work, and involves no abstruse calculation as to the possible effect of each touch. We think that photographers will see advantages in both methods. In Mr. Edwards', in the advantages of a structureless transparency, and also in the softened definition of imperfect contact in printing; and in Mr. Croughton's, especially where much amelioration is rendered necessary to meet the defects of an imperfect original negative.

One fact is, however, beyond question. Within the past year or two enlarged photographs have attained a degree of excellence before undreamed of. The Autotype Company's enlargements, both in portraiture and landscape, of enormous dimensions, possess a beauty altogether unparalleled by any previous work of the kind; and it is but fair to credit the method which involves the use of a structureless film for the transparency with at least something of the excellence. The enlarged portraits of less imposing dimensions, it is true, of Mr. Edwards, are singularly perfect, and to the structureless transparency he attributes much. In both cases, however, it is impossible to escape the conclusion that the skill attained by much experience is an important element in the case. This fact is just as fully illustrated in Mr. Croughton's case. He uses wet collodion throughout, and apart from the advantages involved in his mode of touching at two stages, we have seen untouched results he has produced, which were literally perfect. Fortunately for photographers, the experience of all these gentlemen is at their service on commercial terms. The curious point raised in discussion at the meeting regarding the Autotype Company's tissue is set at rest in another column by a frank statement of the facts.

As we have said, the original question of enlargement *versus* direct work dropped out of the discussion. In the brief allusion made to it on Thursday night, Mr. Aldridge suggested a curiously interesting consideration. He stated, and correctly, that a head eight inches from forehead to chin was, in many cases, in female heads probably always, much larger than life, so that the direct heads at the Crawshaw competition were, in truth, enlargements. The recognition of this fact introduces a new element into the comparisons between enlargements and direct work if the large heads exhibited in the Crawshaw competition be regarded as the exemplars of direct work. It is clear that the comparison was not quite fair to the direct method, and that it must be regarded, in this match at least, as having given many points to its opponent.

### Correspondence.

#### CARBON TRANSPARENCIES.

DEAR SIR.—It was stated at the last meeting of the South London Photographic Society, that our firm did not supply the same tissue as we ourselves used for the production of transparencies; and as half a truth is calculated to mislead, permit us to make a few remarks on that statement.

When we commenced making enlargements, we employed a certain tissue that answered the purpose extremely well.

That tissue we have always sold—its composition is fixed—and it answers all the purposes for which it is sold, as described in the "Autotype Manual."

Nevertheless, thinking something better might be done, we instituted a careful series of experiments, to obtain in carbon transparencies the characteristics which would yield the highest excellence in the enlarged negative.

For some little time we thought a change in the composition of the tissue led to this end, and at that period declined to sell the tissue so varied; but further research convinced us that such was not the case, while it led on to a discovery that secures the exact qualities we desiderate in a transparency. The nature of this invention we decline to indicate; we reserve it for our own benefit in the way of trade—satisfied if we can supply to our customers the best work in the market.

So long ago as May 2nd, we wrote, in the columns of your contemporary, "We are anxious that carbon printing should be practised as extensively as possible, and are desirous of affording every facility in our power to photographers who may wish to adopt what is undoubtedly the 'process of the future;' but the 'speciality' of enlargements in carbon from carbon transparencies not being a process likely to be carried out efficiently, except upon a considerable scale, hardly comes under the category of carbon printing, and we therefore confine instructions in the practice of it to the licences under our patents, although we make no restrictions as to the purchase of the materials, which are at the disposal of everybody for the purpose of experiment."

This paragraph is still literally true. We use for our own purpose precisely the same "special transparency" tissue that we sell; but the particular knowledge that we possess in its application to autotype enlargements we do not communicate. If any misconception exists in the mind of any one on the point (as the South London discussion appears to indicate) it can only be because their information is not derived from reliable sources. Verbally, and by letter, we make the case clear to our customers. If they require transparencies for window decoration, or lantern slides, we advise to buy the tissue; but if, on the contrary, they desire fine autotype enlargements, we recommend sending the negatives to Ealing Dean as the shortest route to that end.—Yours very truly,

Jan. 13th, 1874.

SPENCER, SAWYER, BIRD, and Co.

#### THE PHOTOGRAPHIC SOCIETY.

SIR.—The reply in your last to my note calls for a rejoinder, which I am sure your sense of fair play will give place to. I have the most positive assurance that the determining reason for my retirement from the council was the part I had taken in agitating the question of reform; and the circumstances will, I think, satisfy most of your readers that this is extremely probable, to say the least.

My letter in the *British Journal* appeared Nov. 26th. The council meeting that retired me was held on the 9th of December. I have the best of evidence that that letter was very sharply attacked by some members of the council, and that its suggestions, instead of being looked at as for the good of the Society, were opposed by a majority of the council, as I knew they would be.

On looking over the roll of the council attendance, there were several members whose attendance was less than nine, and one member, to my personal knowledge, only attended at one meeting last year, and I am informed that he has not been more attentive this; but as I was absent from London during the spring months, I cannot reply for them. I have only seen him once since I have been on the council; and one member elected at the last annual meeting has never attended. I do not question the propriety of the higher considerations ruling in these cases; I only deny point blank that I was retired because I attended fewer meetings than others who were not retired. As to the personal motives or other, I can positively assert that, so far as the drawing up of the requisitions are concerned, no personal hostility was a motive in anything done or planned. I am free to say that I myself felt, and still feel, that our President, with all due respect for his scientific reputation and amiable personal qualities, is not the fittest and most efficient man for the post which the Society contains, and I know that his administration has at times called out very lively disapprobation from zealous and leading members of the Society; yet I have always liked Mr. Glaisher out of the chair so much that I am exceedingly reluctant to find any fault with his tone in it; and if the rules of the Society had left any alternative by his retirement at the expiration of a definite term (as we now suggest in the proposed amendments), I should never have had any feel-

ing in the matter; and, further than this, I have not, nor have I ever had, any personal feeling as to the government of the Society. Most of the members of the council are my esteemed personal friends; but I must say (and every member of the council will know that I say the truth in this) that a majority of them were opposed to the reforms demanded. If this is denied, the supposed privacy of council meetings will not prevent me from substantiating it by particular and circumstantial proof.

I can only say for myself that my occupation makes it very difficult for me to attend our Society meetings, and that I not only did not desire to remain on the council, but cannot accept the new nomination so kindly offered me as a candidate for council at the ensuing election. I shall have no "heart-burnings," and hope that our course will cause none; but the efficiency and character of the Society is of paramount importance; and if that demands any such burnt offerings, they must be made, cheerfully or not, unless I greatly mistake the temper of the majority of its members, which I regard as decidedly in favour of radical reform.—Yours truly,

W. J. STILLMAN.

[We must repeat that Mr. Stillman is in error in almost every statement in his letter. Let us, however, before going further, credit him personally with perfect *bona fides* and absence of personal motive in his action in this matter. We do not doubt his honest good faith and good nature in every step. But he is absolutely in error in his statements. He compels us, against our wish, to state proceedings belonging to the council chamber. At the meeting at which his name was placed on the retiring list we were present, and he was not. We were present from the beginning to the end, and we never heard the letter to which he refers mentioned. We emphatically affirm that it was not discussed in council. What members of council may have said before or after, we cannot tell. We have heard the writing of the letter since then styled disloyal, as it seemed that a member of council having reforms to propose, should propose them in council, where they could be carried. The list of attendances was read from the chair, and so far as our memory serves, the lowest attendance recorded was two, Mr. Stillman's having been three times. The chairman's qualifications we cannot discuss here. On the question of the feeling of the council in regard to the reforms proposed by the requisitionists, we must distinctly question the correctness of Mr. Stillman's estimate. We have not heard a single member of council express an adverse feeling to the general aim of the reforms proposed. We may go further, and state that we have not a shadow of a doubt, that had the reforms in question been proposed to the council, they would at once have received favourable attention, and have carried in their broadest spirit, without agitation of any kind.—Ed.]

#### HOT DEVELOPMENT.

SIR.—Whilst, in common with many, we have warmed our iron before using, it has only been this winter we have used it *hot*.

Its advantage is, to give more detail with our usual exposure; or it allows of less exposure—both very desirable this dull weather. Its disadvantage is, it has a slight repellent action, and it is useful to add a little spirit immediately before using.

To use: pour sufficient to cover plate into an old tea-cup (if slightly cracked, or not quite circular, so much the better.) It is desirable the cup should have a handle, and then you can tell which side has been against the fire. In our practice we pour it out just after the plate is placed in the slide, putting that against the camera, and the cup containing developer on the hob, or top bar, and oven on the fire, if a bad one. After posing and exposure, the cup and dark slide are both taken in the dark-room, a little spirit added, and, according to circumstances, used quite *hot*—boiling, in fact—or add to some cold in the usual glass beaker. The first time you get a sitter come late, or on a dull day, and it is desirable to take him, try it, and you will use it constantly.—Yours truly,

Stourbridge.

HOT DEVELOPER.

#### NOMINATIONS FOR COUNCIL.

DEAR SIR,—Will you please permit me to state that in the list of candidates for seats at the council of the Photographic Society proposed by Col. Stuart Wortley, my name has been used without my knowledge, will, or consent. As a member of the Society I have no doubt he was entitled to do it, and I am sure he meant it in kindness; but as I prevented its insertion in Mr. Stillman's list, and, of course, omitted it in my own, I must respectfully protest against its being in that of the Colonel's. Under present circumstances it would be highly improper for me to be a candidate for any office whatever.—Yours, &c.,

JABEZ HUGHES

## Proceedings of Societies.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this Society was held in the Hall, 5, St. Andrew Square, on the evening of Wednesday, the 7th inst., the President, R. G. MUIR, in the chair.

The minutes of previous meeting were read and approved, and the following gentlemen were admitted ordinary members:—Messrs. John Smith, John Aitchison, John White, A. D. Cairns, James Macdonald Hay, William Hislop, Albert J. Allan, Robert Younger, John L. Coulston, Thomas Carnichael, Thomas Dryburgh, William Raeburn, William Paxton, James Taylor, James Storr, W. Rhind, W. Gilmour, George F. Roger, W. Ingles, Councillor Donald, and Alexander Hunter, M.D., F.R.C.S.E.

A letter was read from Messrs. Poulton and Son, intimating a presentation to the Society's album of a large number of very fine photographs, including a series of beautiful cloud pieces. The pictures were handed round for the inspection of the members, and were very much admired.

The President said it was not often that the members had an opportunity of examining such a large number of prints so uniformly fine in quality. They would make their album an ornament to any society, and he had no doubt the members would agree with him in requesting the Secretary to convey to the Messrs. Poulton their best thanks for their valuable donation.

Dr. NICOL then read a paper on "The Progressive Results of the past Session." (See page 25.)

Mr. TUNNY said he rose to propose a cordial vote of thanks to Dr. Nicol for his admirable paper—admirable he must say, with exception of the concluding paragraph, but to it he must take exception. He thought, as a society, they had nothing to do with the opinions of sects as to how the Sabbath was kept, and such statements should find no part in the proceedings of the Society. He did not believe that there was a photographer in the country who had not done some photography on the Sabbath day, and he thought every man should be left to the freedom of his own will in such matters.

Dr. NICOL said that he had no wish to interfere in the slightest degree with the liberty of the subject; every man should be convinced in his own mind as to his duty. He thought that there was considerable difference between the private actions of a private individual, for which that individual was alone responsible, and the public scandal to which he had referred. He had written exactly as he thought; and although he should be sorry to delete the paragraph objected to by Mr. Tunny, he, of course, could do so if it were desired by the meeting.

Mr. TUNNY said he did not wish to divide the meeting on the subject, but would be satisfied if his protest were recorded.

Mr. W. NEILSON, who had taken the chair, as the President had to leave, said that he considered the paragraph one of the best in the paper, and should on no account like to see it deleted. He heartily seconded Mr. Tunny's vote of thanks to Dr. Nicol for the admirable review of the work of the session, and the vote was carried by acclamation.

Dr. HUNTER then handed round a large collection of very fine photographs of Indian landscape and architectural scenery, and gave some most interesting information regarding the subjects, and methods of manipulation. He stated that much attention had been given to dry plates, but that, on the whole, they had not found them suitable for the climate or kind of work; and he mentioned also the curious fact that they had invariably the best results in the higher elevations. Dr. Hunter was cordially thanked for the exceedingly interesting exhibition and the valuable information accompanying it.

Mr. TUNNY then re-introduced his observations and experiments on the action of barytic nitrate on the nitrate bath. He said that his attention had been called to Mr. J. T. Taylor's observations on the subject in his paper on the work of the South London Society, and Mr. Henderson's experiments, as reported in the *Journal*, and on trying to repeat those experiments he was surprised to find that, so far as he could see, the barytic salt did not possess the properties there attributed to it. He had placed a little of an old bath in a test-tube, and, by the addition of a few drops of distilled water, thrown down a slight deposit of iodide of silver. The saturated solution of nitrate of barium was then added, but instead of dissolving the deposit, it actually increased it, by still further reducing the strength of the bath solution. He had also put it practically to the test in the following way:—He had an old bath giving an abundant supply of pinholes, and this he divided in two parts; to one he added the solution of baryta, as recommended by Mr. Henderson, and left the other in its normal state. On taking a negative from a plate sensitized in each bath, he found the

untouched gave a better result than the one to which the barytic had been added, as while there was no diminution in the quantity of pinholes, the plate from the barytized bath was covered with a whitish film, similar to what is occasionally produced when the collodion has been made with an unsuitable variety of pyroxyline.

Dr. NICOL said he had, at Mr. Tunny's request, examined the sample of barytic nitrate which had been used in his experiments, and found that it was all right. He, too, had tried to repeat Mr. Henderson's experiments and failed, and from the little examination that he had been able to make, he was quite sure that the barytic salt did not possess the property claimed for it; his experiments certainly showed conclusively enough that it neither prevented the throwing out of the silver iodide, nor dissolved it after it was deposited.

The CHAIRMAN said that the idea of adding nitrate of baryta to the bath did not originate with Mr. Henderson; he had seen it done years ago by Mr. Rodger, of St. Andrew's, and although he did not know anything as to its action on the iodide of silver, he thought it had, in some way, a beneficial effect on the bath. A few days ago he had an old bath that had been laid aside for many months, and on trial it was found to give a plate completely covered with pinholes. He then added the baryta solution, and on another trial they were found to have nearly all disappeared, although the negative, especially in the shadows, was covered with a whitish deposit.

Mr. Tunny was thanked for his communication, and the meeting adjourned.

### PHOTOGRAPHIC SOCIETY OF LONDON.

The ordinary general meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, January 13th, Mr. J. GLAISHER, President, in the chair. The minutes of a previous meeting having been read,

Mr. STILLMAN objected to them as inaccurate and incomplete.

The CHAIRMAN declined to recognize any general charge of inaccuracy. He would read the minutes seriatim, and ask if each one, as he read, was true or false; and if any specific inaccuracy were pointed out, would be happy to correct it, as he himself, unfortunately, had not been able to be present at the meeting.

On proceeding to read the minutes seriatim,

Mr. STILLMAN again complained of an omission.

The CHAIRMAN said he should be happy to rectify any omission if any member, of his own knowledge, could supply the details.

Mr. STILLMAN was proceeding to read some details from a journal report, when

The CHAIRMAN declined to receive them; he wished for details from any member's personal knowledge.

Mr. VALENTINE BLANCHARD said that Mr. Stillman was not present at the meeting in question.

Mr. STILLMAN said he believed he had already said that he was not present, but he had been informed of the proceedings, in which Col. Wortley asked for certain information, and did not receive it.

The CHAIRMAN again said he had asked for personal information as to the omission.

Mr. STILLMAN, advancing to the chair, tendered a journal, which, he said, contained the details.

The CHAIRMAN declined to accept or recognize the report of any commercial journal as of authority in the transactions of the Society.

Mr. J. R. SAWYER, as having been present at the meeting in question, could, from personal knowledge, confirm the statement as to an omission. Col. Wortley asked a question as to the attendances of the various members of council, which had not received, as he thought, the attention it deserved, and a reference to such a question having been asked should, he thought, find a record on the minutes.

The SECRETARY explained that as he understood the Chairman to rule the question not in order, he had made no mention of it in the minutes, which were simply a record of the order of the transactions, and not a full report of proceedings.

Mr. SPILLER, as having been in the chair on the occasion in question, wished to explain that as the question of Col. Wortley involved a wide enquiry, the discussion of which would have required the whole of the evening, already devoted to other business, he felt it was out of order at that time. It required more consideration than could be then given to it.

Col. WORTLEY said that he asked for a list of attendances of members of council, as some guide in relation to the coming election. The Secretary had since informed him that at the time he asked the question he had not the facilities at hand for furnishing the information, but had since most courteously furnished him with all that he asked for.

The CHAIRMAN said that he considered Mr. Spiller's decision

that the question was not in order was strictly correct. Had he himself been present, he should frankly have supplied all the information he could upon the subject. He liked to see the members interested in such questions, and should like to see at every annual meeting a voting paper placed in the hands of each member, with the attendances of each member of council set down opposite to his name. But as the annual meeting was the proper occasion for discussing business questions, and their ordinary meetings devoted to reading and discussing papers might be seriously interrupted if business questions were obtruded, Mr. Spiller was quite right.

Mr. STILLMAN thought that in any case the question should have been placed on record in the transactions of the Society.

CAPTAIN ABNEY said that a thing of this kind could not become a transaction until it was completed, and as the question had been ruled out of order it formed no part of the transactions to be recorded in such minutes.

After some further conversation,

The CHAIRMAN asked Mr. Sawyer to briefly state the omission as it occurred to him, with a view to add it as an addendum to the minutes. This being done, the question dropped.

Mr. WALTER BIRD and Mr. WERGE were appointed auditors.

Mr. HUGHES called attention to Rule 7, which provided that at the January meeting any member could send in lists of nominations for councilmen in place of those recommended by the council.

The CHAIRMAN having read the rule, invited nominations.

Mr. HUGHES said that in the list of officers retiring and proposed he saw no mention of a president, either for re-election or election.

The PRESIDENT said that by the rules of the Society the office of President was a permanent one. The Chief Baron, formerly President of the Society, said to him at the time when he was contemplating resignation, and he (Mr. Glaisher) was asked to accept the office: "I hold this office for life, or until such time as I voluntarily resign. You will hold it on similar conditions, and you must consider the matter more carefully than if it were simply a temporary office." By the fifth rule, the election or re-election of all officers was provided for, except the President, in relation to whom no such provision was made. He might, however, tell the meeting that he had repeatedly offered to place his resignation in the hands of the council, and they had declined to receive it. He would now say to the members that he would never place himself in opposition to their wishes, and although he had the power to remain President permanently, he would only retain such a position so long as he retained the suffrages of the Society at large. He felt it necessary, however, to explain that there could be no election for President until he resigned.

Three different lists of officers for election at the annual meeting, in opposition to the list of the council, were then handed to the President, who read them to the meeting.

Mr. HUGHES handed in a list as follows:—President, J. Glaisher, F.R.S.; Vice-president, J. R. Johnson; Treasurer, T. Sebastian Davis; Members of Council, Messrs. Elwell, A. Goslett, F. Howard, J. A. Spencer, W. Woodbury.

Mr. STILLMAN handed in a list as follows:—for President, J. H. Dallmeyer; Vice-President, J. R. Johnson; Treasurer, T. Sebastian Davis; Members of Council, Messrs. Elwell, F. Howard, J. A. Spencer, W. Woodbury, Col. Wortley.

COL. WORTLEY handed in a list as follows:—No alteration in President or Treasurer; Vice-President: Dr. Mann; Members of Council: Dr. Farre, Dr. Diamond, Messrs. Stillman, Hughes, and Swan. Col. Wortley also named those he should like to retire, which were, however, with one exception, the same as those proposed by the council for retiring.

Mr. HUGHES wished to give some reasons for proposing his list.

The PRESIDENT said that as each member was strictly within his right in proposing new names, the statement of reasons was quite unnecessary. For his own part, he should be glad to see an actual ballot, which showed that members took an active interest in the Society.

After some further conversation,

Mr. F. W. HART, presuming that balloting lists would be sent out, asked if any provision would be made for country members to vote without being personally present. If such an arrangement were contemplated, he should oppose it.

The CHAIRMAN said that as the rules were silent on the subject of proxies, it would be a question for future decision.

Mr. HUGHES gave notice of a motion at the annual meeting appointing a committee to revise the laws of the Society.

The following gentlemen were duly elected members of the Society:—Col. Maude, Lieut. Chernside, R.E., W. Noel Hartley, and R. V. Harman.

Dr. MANN then read a paper on Dr. Black's observations on and

photographs of the eruption of Vesuvius in April, 1872. A fine series of photographs were shown in illustration, minute and interesting descriptive details of all the pictures as they hung on the walls being given by Dr. Mann. The photographs were chiefly taken on collodio-bromide plates. Great difficulty was experienced, owing to the prejudicial action of the sulphurous vapours on the sensitive surface.

COL. WORTLEY, at the request of Dr. Mann, described the plan he had adopted when photographing the crater of Vesuvius many years ago. He placed another plate of glass in front of his dry plate, separated at the corners by a piece of microscopic glass, and then ran a varnish of marine glue all round the two edges, so as to seal the sensitive surface hermetically from the air. By this means he succeeded perfectly. He thought that a similar plan for protecting plates during the sea voyage on the occasion of the transit of Venus might be useful.

Mr. STILLMAN said that the photographers in Rome, Macpherson and another, who used the albumen process, felt it necessary to seal up their dark slides with varnished paper in crossing a distance of ten miles subject to similar injurious vapours.

After a vote of thanks,

The SECRETARY read a note from Mr. W. H. Watson on producing sepia-toned prints. It consisted in floating the paper on an ordinary gold and acetate toning bath previous to sensitizing.

Mr. J. A. SPENCER asked if any albumen remain on the paper so floated before exciting, as it appeared to him the solution must remove the albumen. The Secretary had not any example of the results, and could not say.

The proceedings were then terminated.

#### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The ordinary general meeting of this Society was held in the rooms of the Society of Arts, Mr. WHARTON SIMPSON, Vice-President, in the chair.

The minutes of a previous meeting having been read and confirmed, Mr. A. C. Burgess was elected a member of the Society.

Mr. B. J. EDWARDS showed some exceedingly beautiful enamelled cameo cabinet portraits, details of the production of which are given in our YEAR-BOOK. After some conversation,

Mr. EDWARDS then read a paper on "The Best Way to Make Enlargements" (see p. 25).

Mr. EDWARDS also exhibited some examples of unmounted and untouched enlargements, and the large negatives from which they were produced and which were also chiefly untouched. Both negatives and prints were exquisite examples of photography.

A desultory conversation followed, in the course of which the objection was raised that when all the retouching was done on the small negative, the manipulation was apt to show very much in the large negative.

Mr. EDWARDS thought that much depended on the mode of retouching. He blended and softened the touches often by stumping with a piece of chamois leather. By avoiding close contact in printing the transparency the effect of touching was also softened. A large lens of sufficient diameter to permit both eyes to look through at once was invaluable in aiding the retoucher to do his work easily and delicately. The graphoscope would do very well, but the lenses were rarely quite large enough.

Mr. FOXLEE thought sufficient attention was not paid to the fineness of the deposit in the original negative when intended for enlarging.

Mr. EDWARDS said that was unimportant, as there were various ways of translating the coarse texture of the original negative into a fine and homogeneous texture in the transparency. Printing without perfect contact, for instance, would effect that.

Mr. CROUGHTON and Mr. FOXLEE both remarked that this would also destroy sharpness.

Mr. EDWARDS said that this would be less the case than some might imagine; but that, for enlarging, the best results were obtained without absolute sharpness.

After some general conversation on this subject, the question of lenses suitable for enlarging was considered; Mr. Foxlee remarking that the Autotype Company did not use a portrait lens. Mr. Edwards stated that neither did he.

Mr. FOXLEE thought that it was much better to make the enlargement from a small image than to make a partial enlargement in the transparency, and then to enlarge that again.

Mr. EDWARDS thought that the enlargement was best made from a small plate.

Mr. BROOKS narrated a case in which he had been unable to get a good result until he produced a diminished transparency, using only the centre of the lens, and made his enlargement from that.

Mr. YORK suggested that the fault was possibly in the lens.

Mr. CROUGHTON said, that in answering Mr. Edwards' remarks generally he was somewhat in a difficulty, as they were not on equal terms. He had described a process in the PHOTOGRAPHIC NEWS a long time ago, and had given it to the public, whereas Mr. Edwards' process was a secret, and the public generally had not each method before them. He thought the advantages of his process were evident in many respects. It involved only the use of the wet process, with which all photographers were familiar; whilst Mr. Edwards' involved learning a new process. The wet process was rapid and simple, and despite all the remarks on texture, he had showed an untouched enlarged negative, at the last meeting, untouched in all stages, which should absolutely show no trace of texture of any kind. All negatives were not suitable for that, neither were all suitable for Mr. Edwards' process. He did not confine himself to one process. Where a negative was good, he used the Autotype method, using their tissue, and obtaining good results, with little retouching. Where much amelioration was necessary, he contended that his method of working, both in negative and transparency, gave the largest scope; the advantage of working on the transparency being that the effect of every touch was seen, as it would appear in the print. Mr. Edwards' process did not inevitably produce good results, as a transparency produced by one of his pupils, which Mr. Croughton showed, would demonstrate. It was also dangerous to negatives, as a broken negative he showed illustrated.

Mr. EDWARDS had produced many hundreds of transparencies, and had never broken one negative, and had never failed in getting contact. They had occasionally broken the transparency plate, but never the negative.

A conversation followed on the relative amount of time consumed in enlarging by each process, and the simplicity of the albumen process. Speaking of the Autotype process of enlarging.

Mr. EDWARDS said it was to all intents and purposes a secret process. It had never been fully described, and the tissue they used in it was not supplied to the public.

Mr. CROUGHTON and others said they had had the special transparency tissue from the Company.

Mr. EDWARDS said a transparency tissue, but not the transparency tissue they use themselves. Mr. Walter Bird told me himself that no one knew their process, and that the tissue they used was not supplied to the public.

Mr. CROUGHTON believed that they had kept nothing back from him, and that he had used their special tissue daily.

Mr. EDWARDS said it was a tissue for transparency, but not the tissue used by themselves.

A conversation on this subject followed, in which several members joined. Mr. York felt satisfied that the Autotype Company would not mislead the public by a pretence of supplying something they did not supply, and Mr. Griggs was certain that any quantity of the special tissue might be obtained by any photographer.

A further conversation followed, after which

Mr. EDWARDS, answering Mr. Croughton, said that in rapidity he thought his process had the advantage, as a number of plates being prepared together and kept ready made the matter very simple, an enlarged negative he showed having been completed, transparency and everything, in thirty-five minutes. As to ease, anything was easy after you had mastered it.

After a further brief conversation the immediate question of enlargements dropped.

Mr. ALDRIDGE called attention to the fact that the 8-inch heads competing for the Crawshay prize called direct were really enlargements, as life-size rarely was so large. The classic standard for the head was one-tenth of the total height, so that an 8-inch head would imply a man six feet eight inches high. He had intended to send some pictures himself, and borrowed a Dallmeyer 7b. As he found heads in nature rarely exceeded seven inches, the difficulty of producing 8-inch heads became great, and compelled him to approach within four feet of the sitter. For such a size he would prefer to enlarge, although within certain sizes he thought qualities were obtained in direct prints which could not be secured in enlargements.

Mr. YORK said he thought Mr. Dallmeyer laid it down as a rule, that in no case should the camera approach the sitter nearer than six feet.

Mr. ALDRIDGE said that the time required was very long. In a bright light one minute and a-half, and in the afternoon not less than five minutes without a stop.

The CHAIRMAN pointed out that Mr. Aldridge had introduced a new element into the mode of estimating the Crawshay prizes, for if the 8-inch direct heads were really enlargements, it was clear that better results could have been obtained in simple life-size.

After some further conversation the proceedings terminated.

## Talk in the Studio.

PHOTOGRAPHY AND THE TICHBORNE CASE.—A history of the various forms in which photography has been introduced in the Tichborne case would make an amusing document. In the most recent allusion to photographic evidence it is subjected to serious ignominy. The Lord Chief Justice, referring to a photograph of "the grotto," said:—"I never was more astonished in my life when I saw the grotto after that photograph." Mr. Justice Lush added, "I should not have thought a photograph could have disguised the place so." The Lord Chief Justice rejoined, "I think it reflects the highest shame and discredit on the man who concocted that photograph." Dr. Kenealy retorted, "Your lordship is now giving evidence." "I am speaking of what I have seen," said his lordship. "That is what witnesses generally do," Dr. Kenealy replied.

## To Correspondents.

STEREO.—So far as we know, Sir Charles Wheatstone had the instrument he exhibited for a short time in the Society's Exhibition in Conduit Street made for his own pleasure, and we have not heard of any intention of making it for sale. The experience you mention is a lamentable one, and very difficult to explain or account for, except on the principle that the public seem to demand in all public exhibitions something more exciting. To the varied and interesting forms of instructive display which the Polytechnic Institution provides, they find it necessary to add lectures, music, dissolving views, ghosts, decapitations, and other mild excitements. The Crystal Palace, to instruction must add operas, concerts, and pantomimes. Any public exhibition which is chiefly designed to instruct, and not prepared with something amusing or exciting, will generally fail. We shall probably refer to your letter again shortly.

SKYE.—It is quite possible to take a portrait with a rapid rectilinear lens in a good light. We have seen some capital open-air portraits taken with it. We believe that Col. Wortley's large pictures were taken with a single lens.

INDIAN.—A variety of causes may tend to produce a lack of brilliancy in your prints. In the first place, they seem to be slightly over-exposed, and also slightly fogged, either from the over-exposure, from diffused light, from the use of a very new collodion, or from insufficient of a restraining agent in the developer. First try reducing the exposure to ten or twelve seconds; if that fail, see that there is no actinic light in your dark-room, or camera, and no unnecessary reflections of light entering the lens. If you are using a new collodion, mix it with an older if possible; if you have none older, add a grain of pyroxyline, and a few drops of tincture of iodine, to each ounce of your collodion, or reduce the quantity of iron in your developer, increase the quantity of acid, or add thirty or forty grains of sugar-candy to each ounce of developer; or use the gelatino-iron developer, or the morphia developer. See various articles on the subject in our YEAR-BOOK just out.

D. R.—A thorough washing with hot water should serve. A solution of chloride of lime may also be used. Every shelf, corner, and cranny should be so washed.

LEO.—Fuse the nitrate, carrying the heat sufficiently far to burn off traces of organic matter present, then redissolve; or otherwise convert into metallic silver.

ARCHER CLARKE.—Many thanks for a sight of the documents. It seems to us that the paper is a collodio-chloride paper similar to that prepared by Obernetter of Munich, and the print resembles in tone and character those produced by Mr. Erico of Dunse, on this paper. After examining the documents again, and making some extracts, we will return them to you, together with the example. Thanks for your portrait.

M. P.—It should be Vol. xvii. The mistake has passed unobserved.

W. P. F. M.—So far as we know, Gemoser has not patented his process in this country; but a process was patented in this country in 1869 by Mr. Rye, which was nearly allied to Gemoser's, and was, indeed, as we have understood, practically the same as Gemoser's. Whether the patent has been maintained by the payment of the fee due at the end of three years we do not know. Our impression is that Albert's process is the simplest. 2. There is no duty to be paid for distilling water, but the use of a still is illegal without the permission of the Excise authorities. It is probable that if you distil water you will not be interfered with, but still it is possible, and it is safer, therefore, to apply to the Excise authorities for permission, which will, we believe, be readily granted.

N. D.—All particulars will be given in due time. There will be a special meeting held. There is no need for antagonism or hard feeling in such matters.

W. HEIGHWAY.—Many thanks; in our next.

W. J. C. MOENS.—Many thanks. We will give the matter our attention.

THE PHOTOGRAPHIC SOCIETY.—A long letter from Mr. Hudson of Ventnor, advocating specific reforms, is compelled to stand over for lack of space. Several Correspondents in our next.

## The Photographic News, January 23, 1874.

## FRENCH CORRESPONDENCE.

THE event of the last fortnight has been the presentation to the French Photographic Society, by M. Leon Vidal, of some polychromic pictures, which he has been enabled to produce by his improved practical method. Between these last specimens and those submitted with his Memoire some time ago there is all that difference which distinguishes a work of art from that of an incomplete result. The modifications made by M. Vidal in his process appear at first sight of little importance; but they have a great influence upon the finished production. My readers may recollect that every one of the clichés helping to form the polychrome is printed upon films of different colours, so that it is made up of yellow, red, and blue images, which are developed, like carbon photographs, upon a provisional support. This last is of vegetable paper immersed in a solution of white shellac (powdered) in alcohol at an ordinary temperature. The image adheres perfectly; no air-bubbles are formed, the transparent paper permitting one to see the air that exists before development between the film and the developing surface. Moreover, as the material has a very close texture, and the coating of shellac fills up the smallest interstice, its impermeability is perfect.

M. Vidal's former mode of operating was as follows:—The image, after development, was passed into an alum solution and washed, and then a thin film of gelatine was applied, and allowed to dry.

To mount the proofs destined to be superposed, and thus to form a finished picture of a polychromic character, M. Vidal recommended the following method of operating:—The monochrome image which is to be placed first upon the permanent mount is taken, and put with this into a bath of pure water which has been properly filtered, both surfaces being withdrawn in juxtaposition; the print is pressed down into position by means of filter-paper, and afterwards the impression is allowed to dry upon the mount in the open air. It is in this method of mounting that the recent modifications made by the author are to be found.

Instead of gelatinising the monochromes, he covers the mount with a thin coating of gelatine, which may be either of carbon tissue, ivory, metal, &c., and then every one of the monochromes which are to be applied. To get them into juxtaposition, he merely places the monochrome to be mounted in the required position, thanks to the transparent nature of the vegetable paper; then he adjusts the glass plate, held in the first place horizontally, upon which the proof is placed for mounting, and the liquid between the support and the image is thus allowed to flow off, and the two surfaces to become dry. The operator must not employ pressure to get the two surfaces cemented together—say, by pressing the image with a sheet of blotting paper—for M. Vidal has found that such an operation is attended with danger, for the vegetable paper stretches unequally, and any mechanical force throws out the images from their proper position. By placing the films one on the other wet, and allowing them to settle down and dry, the sharpest results are attainable.

One may judge of this by the three specimens of polychromic printing which M. Leon Vidal presented to the French Photographic Society, and which have been unanimously admired. They represent the reproduction of a charming painting by Chaplin, and two portraits from life, one of which is printed from a cliché by M. Luckhardt, of which copies in Woodburytype and Lichtdruck are to be found in the treatise on photography which Dr. Von Monckhoven has recently published. The second portrait is mounted upon opal glass, in order that it may be viewed as a transparency.

These specimens are charming, and possess, besides all the exactness of a photograph, the beauties of the finest miniature. The portrait on glass shows us how far the process might be employed in the production of glass stereoscopic slides.

Here, then, is the first step made towards perfecting the process; it is a considerable one, and, moreover, one which will convince the most sceptical, after having seen the results, that polychromic photography exists, and that it is destined to play a part in the future of our art.

The ingenious plan, projected by M. Melchion, to reduce the duration of pose, and of which I gave a description in one of my last letters, has quickly found new partisans. The readers of the PHOTOGRAPHIC NEWS will remember that the method consists in exposing the sensitive plate through a ground glass, before it actually receives an image or portrait upon it, and to increase the image in a twelve per cent. silver solution before it is developed. M. Franck de Villecholle declared, at the last meeting of the Photographic Society of France, that he should in future operate in no other manner, and M. Liebert said as much. These two operators mentioned some slight modifications which they had made to M. Melchion's process. M. Franck adapts to the lens a cap of ground glass, which is employed instead of the plate used by M. Melchion. Quiret employs opal glass instead of ground glass, and modifies his instrument in the following manner:—

The lens is furnished with a cap, the metal rim of which is covered interiorly with black cloth, so as to fit well over the lens, and be easily taken off. In the centre of this cap is pierced a hole, the diameter of which is about equal to the front lens. This opening is covered with opal glass, the ground surface of which is turned towards the lens. In front of the cap is put a screen of black linen, similar to that carried by the doublet lenses of Ross. Fixed on a hinge to the top of the cap, this screen or shutter may be raised and lowered very rapidly, without in any way taking the cap off the lens.

As soon as the sitter has been posed, the focussing proceeds in the ordinary way. The cap, with opal glass and shutter, is put over the lens, and the plate is then put into the camera instead of the focussing screen, and the shutter or screen is raised for a period of from one to five seconds, according to the intensity of the light and the focal length of the object glass. Afterwards the lens is uncapped in the ordinary way, the plate exposed, and the portrait is finished.

By acting in this way, the ordinary routine is but little changed, and the sitter scarcely notices the operation, while the exposure is reduced by at least one-third. It is advantageous before development to plunge the plate in a sensitizing solution of nitrate of silver after it comes out of the slide, and before it is treated with the developing solution.

ERNEST LACAN.

## PHOTOGRAPHIC ILLUSTRATIONS OF THE ERUPTION OF VESUVIUS OF APRIL, 1872.

Collected and Prepared by J. M. BLACK, Esq., J.P. :  
Explanatory Remarks.

BY DR. MANN.\*

THE photographs which are the subject of this communication were collected by Mr. J. M. Black, who happened, by good fortune, to be at Naples at the time of the eruption. A portion of them were made by himself, by a dry process, on gelatine tissue. But those photographs are supplemented, to some extent, by the work of Neapolitan photographers, in order to render the illustrations as complete as possible. The entire series are now placed before the Photographic Society through the kindness of Surgeon-Major W. J. Black, of Edinburgh, the brother of

\* Read before the Photographic Society of London.

the contributor of the photographs, and an old acquaintance and friend of the author of this notice.

The illustrations consist of twenty-six photographs, and represent the different phases of the eruption, the aspect of the great terminal crater of the mountain after the eruption, and the damage done by, and structural peculiarities of, the lava-stream.

The great eruption of 1872 commenced on Wednesday, the 24th of April. At that time the crater was glowing with fire, lava-streams began to descend the cone in various directions, and a column of smoke rose to a great height above the mountain. This state of matters continued during the next two days, the lava-streams advancing steadily downwards along the base of the mountain, rumbling sounds and explosive detonations being heard from time to time, and the ground trembling for miles around. On Thursday night a fresh crater opened out suddenly near the Observatory, bursting up the ground, and swallowing up a crowd of people who had gone up towards the base of the cone to look at the eruption. On Friday the explosions were very violent, being then heard at Naples, and showers of ashes and pumice fell at Pompeii, Cava, and to the south-east. Several craters were now obvious, emitting flames and smoke, and the eruption was about at its climax of splendour and power. The lava at this period ran down in two streams, one towards the south, dividing towards Torre del Greco and Camaldoli, and the other towards the north, also dividing, and threatening Resina, Giorgio, and Cercola. The inhabitants of Torre del Greco were at this time in full flight. The chief stream of lava in the afternoon passed through the villages of Massa di Somma and Sebastiano, sweeping away buildings and whatever obstacles opposed themselves to its path, and gradually piling up an embankment 30 feet high. Towards sunset the pillar of smoke had spread so as to conceal the mountain, and extended as far as Sorrento, towering up in huge, fleecy, cauliflower-like folds of white vapour, 16,000 feet into the sky. Four open craters were emitting flames and ashes on the lower part of the mountain. The ships in the harbour were trembling with the vibrations of the shocks. At this time it was estimated that two hundred people had been destroyed or seriously injured by the lava.

On Saturday the outburst of fire and smoke declined, and clouds of dust and showers of ashes took their place. The entire mountain, and the country for miles towards the north, were obscured by a pall of dust. The volcanic roar and the sound of subterranean explosions were heard twenty miles away. The villages of Massa di Somma and Sebastiano, on the north of the mountain, were at this time half buried; but the flow of the lava had ceased, and the other villages threatened (namely, Resina, Portici, Pompeii, and Reali) were now felt to be safe. They were all, however, deserted by their inhabitants, as were also Torre del Greco and Bosco on the coast, and Ponticelli, Cremano, and Cercola on the north side of the mountain. As many as thirty thousand fugitives from these villages were at this time encamped at Casoria, one of the suburbs of Naples.

On Sunday the mountain was still hidden by smoke, and showers of ashes still darkened the sky. The ashes were lying two inches deep at Caserta and Salerno, and one inch deep in the streets and on the house-tops of Naples.

On Monday the atmosphere of Naples closely resembled that of London in a thick November fog; the sound of horses' feet and of wheeled carriages was muffled as by a heavy fall of snow, and the ashes were in process of being swept up in heaps. The invisible mountain was roaring awfully, the pillar of smoke above its cone was illuminated at frequent intervals by vivid flashes of lightning, and projectiles were cast above the crater to a height of nearly three-quarters of a mile.

On Tuesday there were still subterranean thunder and shocks of earthquake. Ashes and pumice were still ejected in showers from the cone. Thunderstorms prevailed, and heavy rain began to mingle with the fall of ashes.

On Wednesday, the 1st of May, sand and ashes were still falling in Naples, and its streets were enveloped in darkness; but the volcanic roaring had ceased, and fewer projectiles were seen. The old crater appeared to be nearly silent, but four new explosive furnaces were discharging smoke and flame around its site.

On Thursday the eruption had come to an end, thus giving eight days for the continuance of the outburst.

The chief sources of lava during the eruption were two craters, situated one on the old cone and one in the Atrio del Cavallo, the spot to which horses only are available in making the ascent of the mountain, some little distance from the Observatory, and between it and the base of the cone. The side of the old cone fell in, and it was fissured from top to bottom towards the north. A deluge of lava was discharged from the base of this fissure into the Atrio del Cavallo, and then passed on over the villages Massa di Somma and Sebastiano, covering a vast tract of country 15 and 20 feet deep, and at one time threatening the entire east slopes of the mountain. The Observatory stands on an eminence known as the Cantaroni Hill, which is connected with the base of the cone by a continuous ridge. The Atrio del Cavallo, which was reached by the lava almost immediately after issuing from the fissure of the cone, lies north of this ridge, separated from the bottom of Monte Somma by a broad tract of old lava.

The immediate phenomena of the eruption are illustrated by a series of twenty-one photographs. The first gives a view of the mountain from the Strada Nuova, at Naples, before the eruption, showing the cone, Monte Somma, the Camaldoli Hill, and the position of the coast villages at the base of the mountain. A second photograph represents the appearance of the mountain at one o'clock on the morning of Wednesday, soon after the beginning of the eruption, with the two lava streams diverging from the Atrio del Cavallo, on either side of the Observatory, which is situated high up in the angle between the two. A column of vapour, twelve thousand feet high, is drifting to the south over the mountain. The next view gives the appearance six hours later, with the lava advancing as four streams, the two primary ones having subdivided. The villages of Massa di Somma and Sebastiano, now enveloped in the lava, lie on the extreme left of this picture. A dense volume of black smoke rises from a large fumarole in the consolidating lava just above, with the position of the Observatory a little way to its right. The column of steam and smoke is now spread above the mountain in the form of a vast pine tree, between three and four miles high, and is at this time at its greatest phase of development. Another photograph shows the position of the lava streams an hour later, considerably further advanced towards Ponticelli and Naples, and dust-clouds beginning to fall from the fleecy masses of the smoke-column. In the next photograph of the series the appearance at half-past six in the evening is illustrated, when the folds of the smoke-column were drawing in rapidly from their first splendid dimensions, and when the foginess due to the dust-clouds was greatly increased.

On the following morning (Thursday), at ten, the apex only of the smoke-column was visible above the broad, thick mass of the dust-fog, and the lava streams had reached the limit of their flow, as shown in another view. The appearance of Naples, under the still increasing haze of the dust-cloud, on the Friday morning, the third of the eruption, is represented also in its own photograph.

The next picture of the series shows the great lava waste just above the overwhelmed villages of Massa di Somma and Sebastiano, as looked at from the Fosso Vetrana, with the stream just gliding over an inclination to the left, which slopes from above the Atrio del Cavallo directly down to the destroyed villages. Nine other pictures represent different parts of the overwhelmed villages as they appeared ten days after the beginning of the eruption. In two, the north and south borders of the stream are delineated 30 feet high, and bursting through the lower stories of the burnt

and shattered houses. In another view the lava is seen crossing and closing the vista of a street, like a huge railway embankment thrown thirty feet high across the main line of thoroughfare. In all this part of the series the peculiar weird combination of destructive forces by which the volcano operates is admirably expressed. In one place the lava burns to a blackened cinder, in another it dislocates with a resistless thrust, and in another buries up whatever it encounters under tons of half-plastic adamant, or under piles of loose ashes.

The cindery formation of the crust of the lava, due to imperfect fusion and to irregular cooling of a molten mass, is very intelligibly rendered. In one picture is shown the vast width of the main lava-stream overwhelming the face of the country towards the Bay of Naples, after the fiery flood had swept over Sebastiano.

(To be continued.)

NOTE ON SEPIA-TONED SILVER PRINTS.

BY WILLIAM H. WATSON.\*

A LITTLE while ago I was wishful to try if a print could not be made to represent more faithfully a sepia drawing than is the case with ordinary silver prints, and after a few experiments on the subject, which it will be needless to explain here, I succeeded in getting a picture sufficiently like a sepia sketch to satisfy me.

Of the process I have adopted I append a brief description; and I may add that I have found this method of printing much more easily managed than the ordinary one, consisting of sensitizing, exposing, toning, and fixing. In this case the toning is effected prior to the sensitizing.

I use as the basis the "Eagle" albumenized paper; but I have no doubt whatever that other good papers would answer equally well. The *modus operandi* is the following:—

Floate the albumenized papers in the first place on a toning bath for from five to ten minutes, the bath consisting of—

Chloride of gold	...	...	...	1 grain
Water	...	...	...	10 ounces
Acetate of soda	...	...	...	20 grains †

Remove from this bath, and, when perfectly dry (otherwise stains would be produced), sensitize by placing it on a silver bath (30 to 35 grains of nitrate to the ounce of water); then dry the paper again and keep it under pressure till required for use.

After printing rather darker than the finished picture is actually required, the print needs simply to be fixed in a hyposulphite-of-soda bath and washed and dried.

If the print is viewed by transmitted light, it has a fine transparent aerial effect; and, as I have said before, the finished picture has a beautiful sepia tone.

The only important drawback to this process is that the paper does not keep well. Whether the discoloration is owing to actinic action being continued in darkness, or to the action of the silver on the organic matter of the paper, I cannot positively say, but rather think it is due to the latter cause.

NOTES ON PHOTOGRAPHY IN THE ARCTIC REGIONS.

BY LIEUT. CHERMSIDE, R.E. †

WE invariably used an iron developer for wet plates, and it was with these solutions that we had the greatest trouble. They were first much influenced by the impurities contained in the water, as evidenced by their turbid appearance. We also found that if to the acetic acid, alcohol, and crystals of protosulphate of iron, water at the ordinary temperature was added, the crystals, even though previously pounded,

were not appreciably dissolved after the solution had been allowed to stand for a week or ten days. The solutions were therefore made up with water at temperatures from 90° to 120° Fah. and kept in the engine-room; and we found that under these conditions the developer would always act, provided it had been kept for a few days. With freshly made solutions but little result could be obtained, and the deoxidizing action of a ten-grain developer that had been made up for a week was stronger than that of a sixty-grain solution, unless the latter had been made up for at least thirty hours. The solutions were not used until of the dark clear colour of brown sherry, and, once of that colour, seemed to keep indefinitely; whether this was due to persulphate of iron or not, no rustiness or want of transparency ever appeared. Until it had been made up for twenty-four hours the solution was clear and colourless, after which the colour gradually deepened, and it seemed of full power when from four to six days old. When used cold, or at the temperature of the surrounding air, however evenly poured over the plate, a spotted mottled staining was in places always observable, as if the constituents of which the solution was composed were no longer held in intimate mixture. The refusal of the solution, when still colourless, to act at any ordinary temperature was not perceptibly altered by reducing the amount of acetic acid contained in it, which was diminished to a point at which the formation on the film of a dark purple seam showed the necessity of its presence; nor did the addition or withdrawal of alcohol within certain limits produce appreciable effects; so that we concluded that a sluggishness of action was induced by the climate, only to be overcome by mixing the solution and maintaining it at a high temperature.

The proportions used in the solutions were:—

Protosulphate of iron	...	10 to 60 grains
Glacial acetic acid	...	6 to 18 minims
Alcohol	...	10 to 30 "
Water	...	1 ounce

Of course stronger developers were applied to films that had been only exposed for one or two seconds or less, or where, as is often the case in Arctic regions, from the contrast of the objects in the view, their adoption seemed advisable. With instantaneous views under disadvantageous circumstances of light, we found sugar of great use in bringing out the image; it was simply pounded, and a few grains placed in the beaker containing the solution with which the plate was about to be flooded; this substance seemed to stimulate the action of the developer, and also to increase the density of the deposit. Gelatine has, I understand, the same effect; but, unluckily, we had none on board. In intensifying, having no iodide of potassium, no attempt at changing the colour of the deposit was made, but merely that of increasing its density; for that purpose we used the following solution:—

Pyrogallie acid	...	1½ grain
Glacial acetic acid	...	20 minims
Water	...	1 ounce

This solution, like the developer, gained strength by keeping, and acted most powerfully when of the same colour as iodized collodion. I unfortunately imagined that our negatives could be intensified on our return, having no idea what a ticklish operation the removal of the varnish from a film is, and for a long time intensified but few. This process was almost always carried on after fixing, from the difficulty of seeing in the dark room how the work was going on. A few drops of solution of nitrate of silver (30 grains) were of course added. In making up this solution we failed for some time to get a satisfactory result, a flocculent white precipitate of chloride of silver being profusely formed, even with filtered water; water from the engine-room condenser, however, gave a good result after filtration, a flakey brown precipitate of sulphide and iodide of silver that was invariably formed proving harmless and easy of removal.

As might be expected, with fixing solutions we had no

\* Read before the Photographic Society of London.  
 † Some further explanation is necessary here. Albumenized paper floated on such a bath would lose its albumen. Such a bath would not coagulate, but dissolve the albumen, as Mr. Spencer pointed out at the meeting. The chloride of gold might be used in salting the albumen in the manner employed many years ago by Prof. Maconochie.—Ed.

† Concluded from page 29.

difficulty; but washing the film after the removal of the superfluous iodide and bromide was always a very delicate operation. Lukewarm water was very gently poured on from the jug, and, from the presence of light, any indication of the splitting or blistering of the film could be observed, and its occurrence often prevented by the application of heat. At first, indeed, we lost many films in the washings prior to the fixing process; but latterly this was the only critical time, some splitting unaccountably; and we possess instances of negatives where a sudden crack occurs right across the sky in one or two cases, occasioning, luckily, no injury to the view. This contractile tendency of the film might possibly be rendered harmless by using collodion that gives excessively tough films, as that manufactured from papyroxyline. Blistering often occurred in the final washing, but subsided without injury to the negative on the application of even and gradual heat.

Spontaneous drying in the only places where we could store negatives proved an utter failure, even when the films did not absolutely freeze, and negatives were usually dried in the engine room. Great care was required; and it was above all important that the collodion side should be held slightly downwards, as the moisture of the heated atmosphere continually condensing, fell in dirty drops, from which, unluckily, several of our negatives have suffered. The plates themselves also broke in heating, from the cooling action of draughts of air; and with every precaution we lost eight of our best in this way.

The plates had now to be varnished. Owing to our being unprovided with boxes or space for stowing them properly previous to this process, which, on account of foul weather, had often to be delayed for some days, many were damaged before an opportunity of varnishing them occurred. The difficulty of coating a plate with varnish or collodion on board a ship in motion you can easily imagine; both processes, however, had often to be undertaken when, from wind, tide, or the shocks of ice-navigation, there was a considerable amount of motion.

Varnishing usually came off in the engine-room; and the main points to be attended to were these:—To see that in warming the plate the film did not curl up and leave the glass; to see that no drops of condensed vapour fell upon it; and thirdly, after the application of the varnish, to again apply heat at once; without this latter precaution, especially when the general temperature of the room was low, the varnish at once dried with an uneven matt surface; but once mastered, this difficulty never recurred.

The dry plates used were the Liverpool Company's ordinary and rapid; and the chief objection to them was the lengthened exposure necessary, so that not very many opportunities occurred of using them; this, however, need not have been the case had photography been our main object. The films of these plates were as liable to splitting and cracking in washing and drying, as those of the wet plates, and, in cases of blistering, proved harder to deal with successfully. A good many varnished negatives, the films of which are apparently completely fixed, and show no signs of insufficient washing, have undergone a chemical change, which has caused them to fog over completely; even since our return, we have from this cause lost one or two negatives.

I will now, in conclusion, touch briefly on the conditions of temperature, atmosphere, and light that we experienced.

Photography with either wet or dry plates was successfully carried on from June to September, between lat.  $76^{\circ}$  N. and  $80^{\circ}$  N., and at temperatures varying from  $45^{\circ}$  F. to  $25^{\circ}$  F. In cases where, after exposure, the films of wet plates appeared dry or frozen, it was only necessary to redip the plate in the bath for a short time before development.

The state of the atmosphere is, however, undergoing constant and violent changes; for although the rarefaction of the air necessarily diminishes its powers of absorption of heat, both this and its diathermanous power are directly influenced by the degree of moisture present in the atmosphere; and as this depends not on the absolute quantity,

but on the tension of the aqueous vapour contained in the air, the latter determining the distance of the air from its point of saturation, it will be evident that the limits of this variation are considerable. Still the rarefaction and dryness of atmosphere are usually very great; and as on these depend the maxima of both solar and terrestrial radiation, striking alternations and contrasts of heat and cold occur. From these causes the state of the atmosphere is extremely unstable, and there is a great frequency of fog and mist formed over land, sea, and ice; in the former case the high temperature of the moist soil is the cause, and these fogs are at some height above the ground, only clinging to the hills. But the sea-mists, formed from the air heated and moistened by contact with the earth flowing in currents over the cool surfaces of sea or ice, hang very low; they are unfortunately of great frequency, and often last for two or three days.

But of adverse conditions, the most frequent and annoying is one almost invariably present in a greater or less degree, and especially so in the brightest conditions of light, namely, the vibration of the atmosphere caused by the heated vapours that rise from the thawing soil. The currents of air thus formed are of various temperatures, and, by opposing media of different refracting powers to the passage of the rays of light, produce vibrations that effectually blur the image in the negative.

From the unequal densities of the different layers of air in calm and fine weather, when the temperature of the air is above that of the sea, the various effects of refraction are particularly noticeable, and inverted images in the air of various objects, especially of bergs and masses of ice, are excessively common; and as it by no means always occurs that the layers of air in which the phenomena of various degrees of refraction and of total internal reflection take place are horizontal, the images are often inclined at wonderful angles. As these phenomena are generally transitory, patience is often rewarded by a clearly defined view; and, indeed, when the conditions are favourable, the nature of the light of the Arctic summer is such as to fully compensate the photographer for many drawbacks. The light seems very rapid in its action, and highly actinic, the low absorbing power of the air permitting, I presume, the passage of the actinic rays with but small diminution of power.

The amount of exposure given varied in the case of wet plates from half a second to over thirty seconds, and with dry from three-quarters of a minute to several minutes. From various circumstances before alluded to, a very large proportion of our photographs were taken with the shortest possible exposures, as we were seldom able to give over four seconds; for if the camera itself was not placed on the ship or a moving block of ice, still objects in motion were generally included in the view. When able to give what exposure we pleased, eight seconds usually proved sufficient.

The actinic action of the light was undoubtedly reduced when the air was charged with moisture; but under the most unfavourable circumstances in this respect it was still strikingly powerful. The great distances at which objects can be clearly photographed are of course of immense convenience, hills and other features at a distance of ten miles being clearly defined in some of our photographs.

Finally, I may mention that the obliquity of the sun's rays seemed but little to influence the light, photographs having been often successfully taken by the light of the midnight sun.

#### RECOVERY OF SILVER FROM CYANIDE BATHS.

DR. GRAEGER states that there are many methods of accomplishing this object; but none have been so easily carried out or have obtained enough of the silver to be as satisfactory. The process recently described by Ney, in which the silver was precipitated as a chloride by the addition of muriatic acid, had both these faults. The silver was not all precipitated, the subsequent treatment of the precipitate was

not a simple one; and beside, the operation was attended with a strong evolution of prussic acid, which is extremely unpleasant to many persons, not to say dangerous to life.

"By accident," says Dr. Graeget, "I discovered a method of obtaining all the silver in a very simple and easy manner, and one that may be operated by persons who are not chemists. It is based upon an observation made by myself that cyanide of silver is perfectly reduced to metallic silver by grape sugar, provided the solution contains no free alkaline cyanides (cyanide of potassium or of sodium). The cyanide of potassium present is destroyed by adding a suitable quantity of a solution of green vitriol, which converts it into ferro-cyanide of potassium. Then grape sugar will reduce the silver in the alkaline solution. In carrying out this method, the silver bath, which has become useless, is allowed to settle, and is then decanted into a large iron kettle, where it is warmed, and protosulphate of iron slowly added until a slight precipitate (oxide of iron) is formed, which does not disappear on stirring. It is next heated to boiling, and made strongly alkaline by adding caustic soda or potash, if necessary; and a solution of grape sugar is then added gradually until the liquid acquires a brownish yellow colour. The heat is now to be removed, and the precipitate allowed to settle, after which the clear solution is removed by means of a syphon, and the sediment, consisting of metallic silver and oxide of iron, is thrown on a filter, washed, dried, and ignited. This residue is then treated with nitric acid, which dissolves all the silver, and but little of the oxide of iron. The very last trace of silver in the bath is thus separated and dissolved in nitric acid. To test this process, the following experiment was made: 0.85 gramme nitrate of silver was dissolved in 8 cubic inches of distilled water and chloride of sodium, sulphate of copper, sulphate of zinc, caustic soda and carbonate of soda added, together with enough cyanide of potassium to produce a perfectly clear solution. One-third part of this solution was treated with a suitable quantity of sulphate of iron, heated to boiling, and the glucose added. The precipitate obtained, when treated as above and tested volumetrically with chloride of sodium solution, showed 0.238 grammes of nitrate of silver; this takes three times = 0.814 grammes instead of 0.85 gramme taken, or 81 per cent. A second experiment gave 945 per cent. These results are very favourable, especially when we consider that we were dealing with a solution containing only 4 parts of silver in 10,000 of water. It is a striking phenomenon that not a trace of the copper, which was purposely added to test this point, was reduced by the grape sugar."—*Polytechnisches Notizblatt.*

COLLODIO-BROMIDE EMULSION.

M. BUYRON, of Lyons, communicates to the French Photographic Society the method he adopts for preparing collodio-bromide emulsion. As he lacks time and opportunity to carry on further experiment, he trusts others will proceed with the matter where he has given it up. His idea is to imitate in the preparation of the emulsion what takes place with a collodionised plate which is not introduced into the dipping bath until after the film has set; to do this, he prepares the emulsion with collodion in the form of jelly.

He begins by preparing a collodion with bromide of cadmium, according to the following formula:—

Alcohol	...	...	35 cubic centimetres
Ether...	...	...	35 " "
Pyroxylum	...	...	1 gramme
Bromide of cadmium	...	...	3.50 grammes.

The quantity of alcohol and ether may be varied, as it is only requisite that the bromide of cadmium should be maintained in solution.

After standing for a week, he decants the liquid portion into a wide-mouthed stoppered bottle, and proceeds to evaporate the solvent by shaking the collodion in such a way that it adheres and hangs to the sides of the bottle. In this way a uniform evaporation of the whole mass is wrought about, and the formation of a hard skin over the

material, such as would materially interfere with the evaporation, is prevented. When the jelly contains no more liquid than is necessary to divide it, and it has become firm, and allows no more solvent to flow from it, it may be said to be sufficiently evaporated.

In another vessel are dissolved three-and-a-half grammes of nitrate of silver in thirty cubic centimetres of alcohol, which is easily done by simple agitation; this solution is filtered, and then placed in a bottle sufficiently large to contain the whole of the collodion jelly just prepared.

With a bone or ivory paper-knife, the jelly is broken up into small fragments, and thrown into the bottle containing the argentiferous solution, and the reaction is allowed to proceed for two or three days. At the end of this period the transformation of bromide of cadmium into bromide of silver has taken place throughout the whole mass. The jelly is further broken up, and the alcohol replaced by another thirty cubic centimetres, in a few days. Any alcohol remaining is decanted off, and may be employed for any suitable purpose.

It is from this jelly that the collodion is prepared, by mixing it with—

Alcohol	...	...	40 cub. centimetres
Ether	...	...	60 " "
Pyroxylum	...	...	0.20 gramme,

and agitating the whole until a perfect liquid solution has been formed.

Afterwards, the collodion thus sensitised is allowed to remain for five or six hours (of course, in a spot sheltered from daylight), and nine-tenths of it decanted into a second bottle or collodion pourer; it is then ready for use.

If it is desired to add an organic substance of any kind, or an excess of bromide of cadmium, or of nitrate of silver, this should be put into the second collodion before the bromised jelly is mixed with it.

A single washing of the film, after the plates have been prepared, suffices to remove all injurious matter; the collodion is applied, washed, and treated in exactly the same way as any other collodio-bromide emulsion.

ON THE WANT OF SENSITIVE CHEMICALS AND PERMANENT PRINTS.

BY W. T. WILKINSON.

PHOTOGRAPHERS are always lamenting the want of an instantaneous process in the studio, but are very backward in trying any method which the author claims to be a solution to the problem. How many who are hankering after a quick process for portraiture have tried the bromide of silver with the bath, as described by Mr. Sutton, or the emulsion process (wet) of Col. Stuart Wortley, or the supplementary exposure of the sensitive plate to coloured paper or to light admitted through coloured glass, or the plan of removing the diaphragm during the progress of exposure? If any of these or kindred plans were faithfully experimented with and reported upon, the profession would very quickly be able to catch the fleeting expression of the sitter.

Now, with regard to the stability of prints, Mr. Hart, a chemist, who is well known to be a practical photographer as well, has introduced a chemical preparation for the purpose of eliminating the hypo from our prints. Mr. Newton, in America, has recommended the use of nitrate of lead for the same purpose. Still photographers go on in the old way, lamenting over the faded beauty—still loth to go in for permanency.

This very apathy is a direct encouragement for secret processes, as the experience of the last year has shown that photographers will readily buy a secret process when they will not try one which is published free. My object in this article is to urge photographers, when any process is published which seems at all likely to be what it is claimed to be by the author, to try it faithfully, and report upon it through the News. If this is done, the prophecy of Mr. Jabez Hughes will be fulfilled long before he at present dreams of.

## STAINING COLLODION FILMS.

THE idea of staining collodion films is not strictly a new one, having been repeatedly proposed by experimentalists for different purposes. It was proposed in America some ten or a dozen years ago to tint collodion with saffron or turmeric for the purpose of securing greater intensity in the negative. Whether the idea was ever put into practice beyond the first tentative trials of the originator of the idea we are uncertain; but it is tolerably evident that it never came into general use. Some years later it was suggested that saturating the film of a very hard negative with a tint of aniline blue would probably secure greater softness in the print, as the dense deposit, being dyed blue, would more readily transmit light. The use of a yellow varnish has unquestionably been found useful in giving additional printing vigour to weak negatives. At the first glance it scarcely seems reasonable to suppose that the application of a non-actinic varnish all over the negative should give it any additional intensity, inasmuch as the yellow tint of the uniform film of varnish would naturally retard the passage of light equally all over the negative, lights and shadows alike; but, apart from the fact that the slow printing induced in itself conduces to vigour, there is really an actual increase of intensity or contrast to be gained by using a varnish which will communicate a yellow dye to the film. A glance at the actual conditions will show how this happens. All spirit varnishes really permeate, rather than merely cover, the collodion film, leaving a layer of resin not simply on the surface, but permeating or suffusing the texture of the collodion, and the dense portions of the image, being so much thicker than the shadows, act in some degree like bibulous paper. They retain a greater proportion of the resin and of the colouring matter than the shadows. The result is, that the depth of the yellow tint in the lights, where a greater body of it has been absorbed, is considerably greater than that of the shadows, and so an actual increase of contrast is secured.

But there appears to be a probability of a still greater and more important purpose for the practice of tinting or staining the collodion film by Mr. Henry Cooper, as described in the YEAR-BOOK OF PHOTOGRAPHY just issued. As our readers know, Mr. Cooper proposed this plan as a means of superseding the necessity for backing dry plates with a non-actinic pigment. All dry plate photographers are, to their cost, familiar with the fact that those dry plates which have an exceedingly transparent film are subject to the defect styled "blurring," for want of a better term. The defect is the result of the light passing through the transparent film being reflected back, so as to form a blurred image. The application of a yellow pigment at

the back of the plate was found to check this defect, but it was a troublesome remedy. Tinting the film with a non-actinic colour has been found to check the action even more effectually, and without anything like the inconveniences involved by the use of the pigment.

As the result of further experiment, Mr. Cooper finds that the method of dyeing the film which he has introduced may be applied with advantage in many cases to the wet process. All photographers who have had experience in photographing interiors are familiar with the blurred spreading of the light which occurs when a strongly lighted window is opposite the lens, and a similar defect is not infrequently seen where a mass of dark foliage cuts sharply against a mass of bright sky. The addition of an aniline dye to the collodion obviates these difficulties. The mode of securing immunity from the troubles in question is very simple. Mr. Cooper makes a ten-grain solution of rosaniline in absolute alcohol, and of this adds about five minims to each ounce of collodion. The nitrate bath will, especially if excess of the dye be employed, be coloured; but its working qualities are not in any degree impaired by the colouration. The greater portion of the colouring matter will be removed from the negative in the processes of fixing and washing, and may be thoroughly removed by a final rinsing with methylated spirit; but Mr. Cooper has found no printing disadvantages in leaving the tint in the negative.

If the important discovery of Dr. Vogel, as to the value of charging a sensitive film with a colour which absorbs a non-actinic ray, be found applicable in general practice, another still more important use will be found for dyed films in photography, which may have a very important influence on the photography of the future.

## NEW AND EFFECTIVE MODE OF COLOURING PHOTOGRAPHS.

MANY methods of rendering photographs transparent, and colouring them at the back, have been proposed, and some have been patented. Although many of them have produced very effective results, none of them have ever acquired a permanent position in the practice of portraitists. Such methods have, undoubtedly, some special conveniences. Besides being simple, easy, and cheap methods of securing coloured pictures, which please many of the public, there is the signal advantage of perfect retention of the likeness: the finished picture is a photograph suffused with the hues of nature, rather than a photograph covered with colour, and depending on the skill of the artist in applying that colour for the retention of likeness. One serious drawback which has, however, attended most of the methods of making the photograph transparent arises out of the fact that almost all the materials used (varnishes, resins, turpentine, and wax) have a tendency to turn yellow, giving the picture, in a few years, a dull, jaundiced hue. A correspondent, signing "Alpha," sends us brief details of a method of producing a similar effect without the drawback to which we have referred. Instead of resinous substances, he uses gum and glycerine. The enamelled surface produced by the collodion will have a valuable preservative effect. The pictures so produced will not be high art, but they may be pleasing and effective, and meet the purpose of a large section of the public. In such case they must also meet the purpose of many photographic portraitists. Our correspondent says:—

"1. Take a sheet of glass and collodionize it, using a substratum of wax in ether, or its equivalent, to secure final lifting. Let it dry. Take the picture you wish to colour, and on a touching-up easel paint it, many shades too strong to be natural, on the back with water colours, for choice, as they dry quicker than oil; or Judson's dyes will do as well. Bear in mind, the colour must be outrageously strong, or rendering it transparent will make it poor and flat when finished. Let it dry. Take the pho-

tograph so coloured, lay it in a clean dish, and pour over it methylated spirit sufficient to cover it: very little will be required. Let it remain in the alcohol five minutes or more.

"Mix, beforehand, a solution of gum in water, as thick as castor oil. Put it in a dish, and add sufficient glycerine to keep it from cracking when dry—eight or ten drops to one ounce of gum solution.

"2. Now take the photograph, wet with the spirit, without draining, and plunge it into the gum solution. It will turn white at first, but that will be removed subsequently. When dry, and covered both sides with gum, take it, place it face down, colour up, on the glass No. 1; press out the bubbles, and let it dry. Cut round the edges, and mount on cut-out oval card matt, with a white card behind that.

"ALPHA.

"P.S.—This process originated in America, and is not new, though not generally known. The pictures are superior in appearance to water colour drawings. It may be called a modification of the ivorytype, without the two nuisances, gum resins and the glass."

## TWO NEW PRESERVATIVES FOR DRY PLATES.

BY M. DE SAINT FLORENT.\*

SINCE the year 1869 I have employed two kinds of preservatives, which have not, I think, been mentioned elsewhere, as suitable preservatives for dry plates. They are two compounds well known to druggists, and called *ratanhia* and *laudanum* of Sydenham (wine of opium).

*Ratanhia*, which is met with in commerce in the form of an extract, is produced from the root of a plant of the family of polygalæes which grows in the West Indies and Peru, and which is termed the *krameria triandra*. The extract, whether obtained with water or alcohol, is very much used in medicine, because of its astringent properties, which it owes especially to the tannin it contains. This substance, employed in the proportion of ten parts of aqueous extract to one hundred parts of water and ten to twenty parts of alcohol, forms an excellent preservative for dry plate films. It appears to impart sharpness, and perhaps a little hardness to the image, and so as to prevent any excess on this score it is well to employ a strongly bromised collodion.

The *laudanum* of Sydenham, or opium wine, used in the same proportions, gives still better results. Pictures obtained by means of this substance are very harmonious, and present most remarkable gradations of tone.

I have experimented with a view of determining whether the excellent preservative properties of the *laudanum* are in any way due to one of its constituents. The extract of opium, diluted to a suitable degree, allows me to preserve prepared plates for a certain time, but for a much more limited period than the *laudanum*, and the clichés produced are, moreover, in every way inferior. The saffron and other matter which also enter into the composition of *laudanum* of Sydenham have no especial properties of the required nature, and it is only the compound itself that furnishes such excellent results.

The material, as specified in the Pharmacopœia, and prepared by druggists, is what I employ with such good effect. It is probable that the preservative properties of this substance are in the main due to a certain quantity of morphine that enters into its composition. This material, in the form of acetate, has already been cited as a good preservative, but is rejected by many on account of the dangers inherent to its manipulations.

Dry collodion plates treated either with *ratanhia* or *laudanum* of Sydenham in the proportions I have cited will be capable of keeping the film in a perfectly sensitive condition for a period of many months. The plates yield most excellent results with an alkaline developer, especially if the collodion is prepared on the collodio-bromide method, such as that proposed a little while back by M. Chardon.

\* Read before the French Photographic Society.

## Critical Notices.

VITRIFIED PHOTOGRAPHS ON ENAMEL. The Powder and Film Processes. By J. SOLOMON. (London: J. SOLOMON, Red Lion Square.)

THE issue of a manual of enamel photography will be regarded as a boon by many portraitists. In the concise little work before us Mr. Solomon gives details of two distinct methods, both involving secrets, which, we are informed, he purchased at a considerable outlay; and experience, which he has gained by some years of experimental practice. The two methods are described as the powder process and the film process. The first is analogous to that patented many years ago by Mr. Joubert, in which a photographic image is produced upon an adhesive surface, a vitreous colour in powder being made to adhere to the image in different proportions as determined by the action of light; and the second, or "film" process, is that in which a silver image on collodion is converted by toning into an image of platinum, gold, iridium, or some other metal or metallic oxide, the image in either case being finally vitrified by the aid of a suitable flux and a muffle furnace. The information is clear, simple, and complete. No photographer can hope to succeed in the beautiful art of producing enamel photography without the skill gained only by practice; but the formulae and details of manipulation here given will constitute an excellent guide in acquiring the experience which alone leads to success.

## ANIMALS IN THE ZOOLOGICAL GARDENS:

Photographs from Life by F. YORK.

PERHAPS in no branch of photography has the progress been more marked and satisfactory of late years, than in that consisting of animal portraiture. We confess to something like a child's delight in poring over the wonderful series which Mr. York has, with rare patience and consummate skill, obtained in the Regent's Park Gardens. The "wild beast show" of early days is one of the first agencies which stimulates the youthful imagination, and lifts it above the common-places of every-day life; and in going through the examples before us, we are carried in imagination to the uttermost parts of the earth: the arid wastes of African deserts, the jungle of India, the Australian bush, and Arctic snows; and their denizens, successively come before us. Perhaps the leading feature of the animal portraiture before us is this naturalness of aspect, which permits us to think of the wild beast, and not of its cage. But a few years ago it was regarded as a great feat to secure such photographs at all, and we were content to examine with curious scrutiny a tiger, say, taken in full sunlight, where it was difficult to disentangle the bars of the cage, the shadows which they cast, and the stripes of the animal from each other, a design being at times produced as complicated as, if less regular than, a Highland tartan. Here we have no such effects: in many cases no trace of cage or confinement is presented, and the animals might, for all the picture indicates to the contrary, have been taken on their "native heath." In very few cases, except in portraits of the stronger and more ferocious carnivora, are the prison bars intruded at all. The selection of position, aspect, and general bearing are in a high degree satisfactory, and singularly characteristic in effect, and are suggestive of two important qualities in the artist, quite as important here as his skill in photography. Every picture suggests the appreciative spirit in which each position and attitude has been chosen, and the patience which has waited to secure such effects. Nothing, perhaps, more perfectly illustrates, than such a series, how different and much higher are the qualities required in a photographer who aims to embody art qualities in his work than those involved in the mere capacity to work a process, and place a camera at random before any object to be depicted. Very curious are the expressions of the different animals as they are caught, as

they pause whilst their attention is suddenly gained. The antelope, with steps just arrested, ears pricked forward, raised head, and starting eye, seems alike surprised and startled. The Brahmin cow, and others of the same family, look round with lazy indifference. The wolf comes to the entrance of his den with aspect half furtive, half defiant. The seal, with gentle docility, goes through a performance at the instigation of his keeper. The smoking monkey indulges in his pipe. The chimpanzee, seated on a tree to which he clings very humanly with his hands, looks very like a costermonger claiming, truculently enough, his rights of poor relationship. There is a singularly quaint humour in the appearance of the Typhon heron with his long beard, perched solitary, on a rock, like an eccentric seer proclaiming desolation to some erring people. Lions, lionesses, and tigers are here in grand variety, with superb aspect of lofty contempt, even in their captivity.

Leaving the question of characteristic portraiture, upon which we might dwell at much greater length, some especial words are due on the technical qualities of the photography. Avoiding, in the majority of cases, the distracting effect produced by the intense light and shadow of direct sunlight, we have here in many places the perfection of photography: fine lighting, perfect modeling, full detail, great brilliancy, and satisfactory light and shade. Upwards of twenty years ago the Comte de Montizon, in the very earliest days of the collodion process, secured a few instantaneous photographs of some of these animals. They were admirable works for the time, and were greatly admired; but what an amazing contrast between the results of then and now! It was to these early attempts Mr. Glaisher referred when, in delivering the medals, he spoke of the great superiority of the animal portraiture of Mr. Hedge, and when an unfortunate misconception of the intention of the allusion gave cause of annoyance to so excellent a photographer as Mr. York. A large number of the series before us are new, having been produced during the last year, whilst others were taken afresh. Fine as were the former pictures, we fancy we can find minute points of technical superiority in the most recent examples, showing how, in work of this kind, practice leads to perfection.

Mr. York has also increased his series of London stereographs, especially adding a very complete set of views of the Tower. Our space does not permit us to notice them in detail.

**THE AUTOTYPE PROCESS**, being a Practical Manual of Instruction in the Art of Printing in Carbon and other Permanent Pigment. Third Edition, Revised and Enlarged.—(London: SPENCER, SAWYER, BIRD, & Co.)

This is a new edition of the Autotype Manual, considerably amplified. It contains a fine portrait admirably illustrating the excellence to be secured in carbon printing, and a capital photo-collotype illustrating a chapter by Mr. Sawyer in the mechanical process employed at the Autotype Printing Works. We need scarcely say that every one interested in carbon printing—and every photographer should be—ought to possess the work.

**PHOTOGRAPHY IN FOUR LESSONS: A Book for Beginners and Advanced Students.** (London: J. SOLOMON, Red Lion Square.)

This is one of the most compact manuals of instruction we have seen. The four lessons are devoted to the production of collodion positives, the production of negatives, printing on paper, and the production of enlargements. The few introductory words describe the aim and character of the work very clearly. Here they are—

“This is chiefly a book for beginners. It does not deal with the history of photography, nor its theoretical principles, nor its manufacturing chemistry. The beginner will purchase his apparatus and materials ready made; mix his preparations as we shall

direct, and use them as we shall instruct him, his sole object at present being to take pictures. When he has accomplished this, he will begin to inquire upon what principles the art is based, and make some practical experiments in its chemistry. But he will begin by learning the practice. A man learns to talk before he studies grammar.”

The lesson on enlargements is unusually complete and valuable, and contains, amongst other valuable hints, a chapter on producing transparencies for enlargement by means of an albumen process, which is worthy of especial attention.

**PHOTOGRAPHY MADE EASY: A Manual for Beginners.** By W. F. STANLEY. Second Edition. (London: W. F. STANLEY, London Bridge.)

WE noticed some months ago the first edition of this useful instruction book, and we have pleasure in again commending it to our readers in a second edition.

**LETTS' DIARIES for 1874.** (London: LETTS, SON, & Co., Limited.)

THE recent demands on our space have delayed some pressing notices. It is getting late in the year to call attention to this very complete and admirably convenient series of diaries, almanacs, and pocket books, is as perfect as ever, and, as it has been for so many years past, is issued in almost every form which the convenience of the public can demand.

### Correspondence.

**DISAFFECTION IN THE LONDON PHOTOGRAPHIC SOCIETY.**

DEAR SIR,—I thank Mr. Hooper for his complimentary reference to me in his letter of last week on the above subject. I have read most, if not all, of the letters which have appeared in your issues, and these prove that “disaffection” exists; whether it is “deep-seated” or not it would be presumptions for me, a countryman, to say. Perhaps, however, you will kindly give me space in which to state my view of matters, and to make a suggestion or two, which may or may not be considered appropriate.

Mr. Hooper has well pointed out that, owing to a most admirable suggestion of his, an alteration was made in Law 9, and no less than twenty-two members joined the Society in December, 1872. I do not know whether Mr. Hooper was then a member of the council; I infer from his letter that he was not, and if not, it will be at once seen that a very valuable suggestion, immediately resulting in the addition of twenty-two new members, emanated outside the council. Let it be understood that I do not say this by way of disparagement in the least, but only to show that the infusion of new blood into any organization awakens, refreshes, and invigorates.

I believe that institutions of almost every sort, if left to themselves, are much too apt to get into a sort of conservatism and routine, from which it is unusual for them to arouse themselves; and if any outside influence attempts to shake up this torpor, it is looked upon as an unwarrantable interference with (almost) vested right—is considered as an intrusion or meddling without due reason, and is resented as such. I am only here stating what I consider the inevitable tendency of systems that are reared on too narrow a basis, without attributing blame to individuals.

Now, sir, to reduce theorising to practice, do the above remarks apply to the London Photographic Society? I believe they do; and with your permission I will point out one or two things which, in my opinion, are susceptible of improvement; at the same time let me say that I do it with great diffidence, because I am so young a member of the Society, and because, living so far from London, I am necessarily absent from its meetings, and but slightly acquainted with its *modus operandi*.

In the first place, then, I would alter Law 7—“Election of Officers.” It says:—“The council, at the ordinary meeting in December in each year, shall declare the names of the members of council whom they recommend to retire, and lay before the Society the names of those whom they have selected to supply their places. They shall also declare the names of the other officers they recommend for re-election, and cause a list to be suspended in the meet-

ing-room. In the event of any member of the Society being desirous of proposing other names than those recommended by the council, a written list, &c., &c., shall be publicly suspended with the list recommended by the council." &c., &c.

In the above clause lies, I think, the root from which the present dissatisfaction has grown; and Mr. Hughes has very aptly put it in his letter of the 19th ult., where, in speaking of this mode of election to the council, he says that the members can provide "opposition lists." I would suggest that the council do *not* recommend any to retire from the council, do *not* prepare a list for election, and do not recommend other officers for re-election; all this should be done by the members. Only one list should be prepared, and that in the way of the members sending in the names of their candidates to the secretary before a fixed date, who shall make *one* list without distinction of name of nominator. This plan would, in the matter of elections, place every member on a level, and the council would have the same right to nominate and vote as their fellow members, but no more. I have been a member of a literary society for fourteen years where this plan is adopted, and it has always worked well.

I further think that the retiring members of the council should go out in regular rotation, and the best men are sure to be re-elected. It may be a question whether the secretary should be elected by the members at large, or by the council alone. I do not know how many meetings the council hold every year, but if he is more intimately connected with the council than with the members, perhaps it would be wise for the council to elect him, as, of course, they should work in union; but that may be a matter for discussion.

One more point I should like a word upon, if I am not trespassing, viz., the mode of election. Why should we country members be debarred from voting? The answer, perhaps, would be that it would neutralize the ballot; but, sir, I think both ends could be secured by the secretary sending to each country member a printed list of the candidates, with instructions to scratch off the names not voted for, and return, under cover, the voted list. These could be marked on the outside of the envelope, "Voting Paper," and only opened at the electing meeting by the presiding officer, who would put them unopened into the voting urn; and, mixed up with the others already there, who could tell whether I voted for Mr. A. or Mr. B.?

I hope, sir, that, because I have made the above suggestions, you will not conclude that I have retreated to that "veritable cave of Adullam" to which you refer in your issue of the 2nd inst. I have pleasure in repeating my words of more than a year ago, that "we ought to strengthen the hands of the council, who take no pecuniary remuneration for their arduous labours, but who certainly, at the very least, ought to receive the grateful commendation of those for whom they labour." I believe "they have the good of the profession (and not their own ends) at heart."

To secure to the utmost these ends, let the Society be placed on the broadest possible basis consistent with efficiency, and I believe the hands of the council will be strengthened, and the "advancement of the art we so much love" will be greatly promoted.—I am, dear sir, yours truly,  
F. HUDSON.

Ventnor, Isle of Wight, January 12th.

[There would be unquestionable advantages in some of our correspondent's suggestions, and we should especially support that in the last paragraph of his letter, providing the right to vote of country members. He is in error, however, in some points. In regard to the council, for instance, we never knew a less conservative body, nor one more ready to adopt new suggestions for the advantage of the Society. Such suggestions as those made by our correspondent, if sent to the council, would at any time have met with consideration. In proposing rotation as the sole rule of retirement we think our correspondent is in error, as by following it the Society would at times lose efficient and earnest officers, and retain many who perhaps never attend a single meeting of council. Regularity of attendance at council meetings, as well as seniority and rotation, should govern retirement, and as the existing council alone can know various points of this kind, it becomes its duty, and is the rule in all scientific societies, to recommend officers for retirement. Facilities of the widest kind, and free from all taint of invidiousness, should exist for members electing new councilmen, and there may generally, with advantage, be an infusion of new blood every year. As it is probable that the whole question will come before the Society, members will have an opportunity of making the laws on as wide a basis as they choose.—ED.]

#### ELECTIONS AT THE PHOTOGRAPHIC SOCIETY.

SIR,—I beg that you will give publicity to the fact that although my name has been published as a candidate for the office of President of the Photographic Society, it appeared without my having been consulted, and without my permission having been obtained; and, further, I distinctly decline the proposed honour, desiring that my name may be expunged from the list.

I have written to this effect to Mr. Stillman, the proposer of the list in question, as also to the President and to the Secretary of the Photographic Society.—I am, sir, your obedient servant,

J. H. DALLMEYER.

19, Bloomsbury Street, W.C., Jan. 17th.

#### THE PROPOSED NEW MEMBERS OF COUNCIL.

SIR,—Seeing in your last issue that my name has in two instances been proposed as a member of the Council of the Photographic Society, I beg to say that, although I feel the honour thus conferred on me, I regret that circumstances would not allow me to fill the position in such a manner as I think it ought to be done.

WALTER B. WOODBURY.

Greenhithe, January 20th, 1874.

#### THE PHOTOGRAPHIC SOCIETY.

SIR,—In the editorial remarks on the meeting of the Photographic Society, you object to a gentleman who was not at the preceding meeting making any remarks about the inaccuracy of the reports of that meeting in the Society's Journal. It has always been represented that the Journal was printed for the benefit of those members who could not attend the meetings; but if we, who are prevented from attending the meetings, are not to know if they are incorrectly reported or not, what confidence can we have in the record for which the Society has to pay?

I objected to the minutes being confirmed until I was informed whether the grave discrepancy between its report and that of a merely "commercial paper" was owing to inaccuracy in our Journal, and I distinctly stated that I wished to be so informed. The President, with his usual overbearing and despotic manner when anyone advances ideas opposed to his own, took up the matter *ex parte*, as he generally does, and demanded of me to produce evidence in a matter with regard to which I wanted information, and, with that peculiar leonine manner which generally succeeds in cowering all opposition, insisted in pushing me to the wall as a culprit. Other members of the Council came to his aid to prevent the meeting being enlightened, and to stifle discussion on the subject, until Mr. Sawyer, who was present at the former meeting, came to my aid, and Mr. Glaisher, finding that it was not going to be so easy a matter to extinguish me as he had thought, and that the large majority of the meeting was with me, subsided into his unofficial urbanity.

If it was "unfortunate" that I tendered a commercial journal, that misfortune is due to him who asked me for evidence when he should have asked the chairman of the evening; and if the discussion took an unnecessary asperity, it was owing entirely to the manner in which the President took it up. I am not partial to being "sat down on," and the man who tries the experiment does not find me so much like a mollusc as a porcupine; and Mr. Glaisher's manner of performing this feat is, despite your encomiums, characterized neither by "suavity," "firmness," or "knowledge of the forms of public business;" but is—and I call on all men who have been compelled to oppose his ideas, either in the Council or in the Society, to bear witness—rude and arbitrary against an individual whom he does not favour, and the reverse of firm when opposed by a majority; while his rulings are frequently absurd, and he continually takes up questions raised before the Society as a partisan, which, as the presiding officer, he has no right to do. When he asked for specific information as to the inaccuracy of the minutes, and I mentioned the omission, he ruled that an omission was not an "inaccuracy"! And he frequently makes rulings as absurd as this.

His decision (and your opinion) that he is elected President for life is equally unfounded in any plain reading of the rules: "All officers shall be annually elected, with the exception of those who do not go out of office by rotation or otherwise;" but as the President does not go out of office by rotation or otherwise, he is not to be elected "annually," but for such time as the Society may see fit to designate. But no man can base a claim to life appointment without an explicit sanction of the laws. According to the actual rules, which are the most clumsy and ill-constructed that, in a considerable experience of deliberative bodies, I have ever seen, the President is to be elected whenever the Society please

to elect him, and he may be changed at every meeting if they so decide. To maintain that the President does not go out because the rules do not say when he shall go out, is to maintain that he can never be replaced because the rules do not say that he is to be considered as vacating the office after death. It is quite sufficient that the laws do not say that he holds during life or until resignation.

As to the discrepancy between the nominations of the reformers in the Society, and their opposition to the Council's nominations, you make a mistake. *We have never pretended that a non-resident member should be excluded from the Council*; to do so would be unjust. We desire to see new and independent members of the Society continually introduced in the Council, and it has been very broadly asserted that the nominations of the Council have been determined by the sympathy of the nominees in the policy which the reform is intended to replace with another, broader and more in accordance with the interests of the Society; and we take it for granted that if they are friends of the present system they will not favour the reform we desire. We knew Mr. Elwell as an intelligent writer on photography and a clever photographer, a new man, and we put his name on the list as such, without any communication with him.

It is incorrect also to say that every one of the opposition lists contain "some" names on the Council list. The list of the requisitionists and my own contain but one—that of the Treasurer; all the new nominations for members of Council differ from those of the Council.

In reply to your foot-note to my letter in your last, permit me to say that the fact of my letter on the reforms not being mentioned in Council proves nothing; it was not likely to be openly discussed, as I had friends in the Council; but I was warned before the meeting that my letter had been ill-received by the Council (as I knew it would be), and I did not attend the nominating meeting purposely, that there might be no obstacle to throwing me overboard, which, for good reasons, I preferred to retiring myself, as I had previously determined to do. At the meeting of Council called to consider the requisition which I was persuaded, against my wishes, to attend, the manner of the majority of Council was studiously cool and offensive, and that of Mr. Glaisher rude and overbearing in the highest degree—even insulting; and at the adjourned Council meeting (which I did not attend) Dr. Mann and Mr. Whiting, who presented an amended requisition, were similarly received, and both resigned the next day in consequence. A few weeks previously Mr. Le Neve Foster, one of the oldest and most earnest members of the Society, resigned in consequence of what he considered discourteous treatment of a suggestion of reform in the management of the Journal. All this will show how friendly the majority in the Council was to reform.

The first requisition was made as vague as the rules permitted, expressly to leave the Council and Society at liberty to modify the measures proposed without direct conflict; but the large majority of the Council, so far from being actuated by the "broadest spirit," or favouring the reforms, raised every quibble against the requisition, and finally declined to comply with it because it was not exacting enough; and in this opposition Mr. Glaisher was the most earnest—perhaps violent would be the word. I assert unreservedly that the majority of the present Council was opposed to the reforms demanded by the requisition, and that the determination has been expressed to "fight us to the bitter end."

You say the reforms in question would have been received favourably by the Council, and have been carried "in their broadest spirit." Why then were we told that the dissatisfaction which demands them was only the feeling of a few discontented persons, and why should the Council make an act of hostility of their proposal in the only form permitted by our laws? Has the Council so become the master of the Society that its dignity is outraged by a requisition which it is in the clear right of the members to make? Is the Council to become a higher caste among us, that its dignity will not brook being told what it shall or shall not do? The officers of the Society are but its delegates, and their title to the gratitude of the Society is in their doing well and gracefully the service committed to them. Any dictatorial airs or appearance of hanging to office as a right is sure, if submitted to, to injure the efficiency of the Society, and, if protested against, lower the dignity of the officer. A council that does its work thoroughly when in office, and when it goes out does so with a cheerfulness as complete, is sure to do the most good in a society constituted like ours.—Yours truly,

S. Altenburg Gardens, S.W., Jan. 19th. W. STILLMAN.

[We regret that Mr. Stillman forces us into a position which is

very distasteful to us. He blunders most egregiously. He is at once inexact in statement, erroneous in deduction, and, as we feel assured, altogether wrong in the opinions he expressed. Unfortunately, he is, moreover, dogmatic in the exact ratio of his inaccuracy. And—*hinc illa lacryma*—he compels us to say so. He confounds the "minutes" with a "report" of the discussions. Had Mr. Stillman made an enquiry as to the accuracy of the minutes, he would have been in order; but, instead of making an enquiry, he distinctly challenged the accuracy of the minutes, although he admitted he was not present at the meeting to which they referred, and knew nothing whatever about them except by hearsay. It surely needs no argument to show that Mr. Stillman assumed a false position. We repeat, therefore, that it was "unfortunate" that a jarring chord should have been struck by such an irregularity, and that it was indiscreet to offer as evidence a journalistic report of the accuracy of which he personally knew nothing. If his object were to institute a comparison between the report he produced and that in the Society's Journal, he was still more irregular, as no question of the Journal was before the meeting, but simply the minutes, which constitute, as everyone knows, a brief official summary of actual transactions, not of discussions. Omission of details of discussions in such minutes is certainly not inaccuracy, and Mr. Stillman must be singularly unfamiliar with the business of scientific meetings if he fancies that the official minutes of a society should constitute a record of its discussion.

We cannot discuss the Chairman's character or conduct with Mr. Stillman here, as we can scarcely expect him to admire very fervently the firmness with which his irregularity was repressed. Mr. Stillman dogmatizes on the tenure of the President's office. We will content ourselves by saying that we accept, in preference to his exposition, the ruling of the late Chief Baron, upwards of half a century of whose life was spent chiefly in the accurate construing of the meaning of laws. In any case, the question needs no discussion, as the Chairman, although holding his office for life, is prepared to surrender it at any moment to the Society.

There is one sentence placed by Mr. Stillman in italics to give it especial emphasis. He says: "We have never pretended that a non-resident member should be excluded from the Council; to do so would be unjust." This statement is opposed to facts within our own knowledge. The gentleman whose name stands at the head of the requisitionists, in conversation with ourselves, made this a leading complaint against the nomination of the Council of Mr. Swan, who, however distinguished, he said, was resident in the country, and not likely to attend the meetings. Regarding Mr. Elwell, we probably have had more communication with him than his nominators, and not only endorse all they say in his favour, but at any time would have pleasure in voting for him.

In relation to our statement that some names proposed in the new list were identical with those proposed by the Council, Mr. Stillman first denies its accuracy, and then proceeds to prove, by admitting that even his list contained one such name, that in spirit at least our remark was accurate. We give him the full value of the quibble on the word "some."

Mr. Stillman again repeats that he was placed on the retiring list because of a letter he had written, although he now admits that it was not—as he before affirmed—discussed at the Council meeting. We repeat, that having been present at the meeting, we never heard his letter named, and that he was placed on the retiring list because of scant attendance.

In regard to the disposition of the Council in relation to reform, he admits a foregone conclusion, and is, therefore, the worst possible kind of witness; and the fact that he had been little in attendance at the Council does not increase the value of his evidence. He knows that we feel debarred, by our regard for the privacy of the Council room, from discussing the proceedings within its walls to which he refers; but we are bound to affirm that we have never seen anything of the "coolness," "offensiveness," "rudeness," nor "overbearing" manner to which reference is made, and can only suggest to Mr. Stillman that his foregone conclusion he had done something offensive, which he confesses, led him to imagine these things; in short, that they are subjective, not objective, phenomena. So also in relation to the first requisition: there was no opposition whatever. Mr. Stillman says the requisition was vague. That is true: it was so vague that it was illegal, and could not be acted on. As proof of an absence of antagonism, the Council, in order to avoid the delay which the informal requisition involved, invited the requisitionists to meet them, with a view to co-operate with them in securing the desiderated reforms. This the requisitionists declined, and, by doing so, at least gave colour to the statements which have been circulated, that the agitation originated with

some discontented men, whose object was antagonism to the Council more than reform. Our knowledge of the members of the Council, officially and personally, extends over a much longer period of years than Mr. Stillman has known the Society, and we repeat our conviction, based on knowledge—not conjecture—that the majority of them would have been willing at any time, and are now willing, to accept any reforms which may conduce to the prosperity of the Society, and also to acquiesce in, and aid in carrying out, any change which a majority of the members may desire, even should such changes not entirely chime with their own convictions. The statement that the Council have ever expressed an intention “to fight to the bitter end” is not only untrue, but is the exact opposite of the truth. No such sentiment has either been entertained or expressed by the Council as a body, nor, have we reason to believe, by a single individual connected with it.—Ed.]

SUNDAY PHOTOGRAPHY.

SIR,—The report of remarks made by Mr. Tunny at the close of a paper read before the Edinburgh Photographic Society on the evening of Wednesday, the 7th inst., contains the following words:—“He (Mr. Tunny) did not believe that there was a photographer in the country who had not done some photography on the Sabbath day.” I feel it my duty to enter my indignant protest against this sweeping clause.

Of Mr. Tunny's own practice I know nothing; but I believe that not a few of us are still old-fashioned enough to regard as obligatory the words, “Six days shalt thou labour and do all thy work; but the seventh is the Sabbath of the Lord thy God.” For myself I can say that I have never, directly or indirectly, put my hand to the work of photography on the Sabbath day.—I am, sir, your obedient servant,

GEORGE BRUCE.

Dunse, 19th January, 1874.

DRY PLATES.

MY DEAR SIR,—Your correspondent F. R. is good enough to mention my publication on dry plates, and he desires more precise details regarding the degree of desiccation possessed by plates prepared by different dry plate processes.

At the first glance one might be disposed to look upon such a question as a joke, for when we talk of dry plates, we mean plates covered with a preparation perfectly dry; nevertheless, as there are authors who have maintained that in order to remain sensitive the prepared plates should not appear to be perfectly dry, the matter merits discussion.

As far as my own experience goes, it is impossible to prepare plates which will keep well and yield good results without they are dried thoroughly and uniformly. The question, therefore, remains whether the drying should be accelerated, or forced artificially, and whether such a mode of drying is advantageous.

I know that the inventor of the coffee process, Colonel Baratti, has stated that plates dried rapidly were more sensitive; but I myself have never found any advantage to be possessed by such plates. I must, indeed, on the contrary, affirm that every time that I dried my plates artificially and quickly, I only obtained bad and unequal results; when only a current of air was employed for the purpose even, I obtained them almost altogether insensitive. It is with some amount of conviction that I recommend, therefore, a mild and gradual drying of the film, such as I have indicated in my publication; and never to employ plates which are not perfectly dry, for I have mentioned a method of discovering whether this is the case or not.

But to revert to the opinion of Colonel Baratti: I know that he was of necessity compelled to accelerate the drying of his plates (as he himself acknowledged) in order to employ the same in a perfectly dry condition, and this is the reason for his believing in an augmentation of sensitiveness.

I remember that to prove that the drying was perfect he put the dry plates into a baker's oven, and he informed me that after being kept some time they answered well, but he never said that such radical treatment was capable of producing instantaneous pictures.

In any case, we may infer that when one speaks of dry plates, these words should be taken in their complete meaning.

Lausanne, Jan. 19th, 1874.

A. DE CONSTANT;

A PITCH AND BOILED OIL PROCESS—A SEASONABLE HINT.

DEAR SIR,—In offering the above process to my photographic brethren, I beg to say I have not placed it under patent restrictions, which I cannot but think a great mistake, for my knowledge

of human nature teaches me that everything is valued according to its cost.

I may instance your most beautiful “collodio-chloride process,” which was most generously given to the photographic world, and which has met with but a cold reception.

Had photographers been compelled to pay £10 or £20 for the privilege of working this process, such eagerness would have been evinced, and an enormous benefit conferred on photography by the practice of what is really a permanent printing process.

Now for the pitch and boiled oil. Take two pennyworth of the former, and quarter of a pint of the latter, and simmer in a pipkin until the two are united and form rather a thin liquid; then, with a sash tool, go over those parts of your studio which are not water-tight; even broken glass in a skylight.

I have a glass room with a flat roof, which has cost me a little fortune in paint and putty, and which has been the bane of my life for a considerable time, in consequence of the rain coming in, in all directions. Well, sir, for an expense of eight shillings, seven of which was for labour, I have rendered it perfectly water tight, even in this horrible weather, anticipating not gratitude, but scathing remarks for the want of novelty in the suggestion.—I beg to sign myself, your obedient servant,

NO NAME.

THE CHEMICAL ACTION OF LIGHT.

SIR,—Again and again has this subject been discussed and speculated on, but the action of light still leaves darkness on our minds. Any new thoughts may prove useful to elucidate the knowledge sought, so I contribute what has for a long time passed through my mind.

We know that all substances reflect light according to their various surfaces, the effect of which on our brains is to give form, colour, and distance. The chemical rays in like manner as reflected from surfaces, and more or less affect various sensitive films, and in an infinitely stronger way from direct sunlight. What if these hitherto called chemical rays should prove to be the electric part of light? We know that their effect is even retained on prepared surfaces, and can be given off again from these surfaces, though for some time taken away and covered up from the influence of light. What if the invisible change, hitherto concealed from our minds, should be to convert a faintly acid or neutral state of the sensitive film, be it what it may, to an alkaline state, and thus allow silver to be deposited on those parts rendered alkaline by the electric action of the rays of light, while it is not deposited in those parts left unaltered, in an acid or neutral state. It is unnecessary to detail results well known to photographers, which are all explained, if this theory be a correct one; and if correct, would it not, again, be another proof of that contrary action by means of which the Maker of all things always cause nature to work?

W. J. C. M.

Talk in the Studio.

NOMINATIONS AT THE PHOTOGRAPHIC SOCIETY.—Col. Stuart Wortley writes to explain why he placed the names of certain gentlemen on his nomination list, at the Photographic Meeting, who have since declined to accept the nomination. He based his action, he states, on Parliamentary experience, where he learnt the importance of an active opposition “to keep the Government up to its work.” He therefore nominated to office two gentlemen he believed to be the originators of the agitation, or, at all events, the two principal actors in it. Without discussing the question at length, we may point out that the analogy between Parliament and a scientific society fails, as there is little in common between their purposes and action. The continued existence of “an opposition” in the Photographic Society would be simply destructive of every purpose of the Society, and also of the Society itself. In the real or fancied existence of a grievance, agitations may occasionally arise in any society; and in such cases the sooner they are ventilated, and the questions settled, the better, and the sooner afterwards that “oppositions” are forgotten, the happier for the society.

THE DISPUTED ACCURACY OF THE “GROTTO” PHOTOGRAPHS.—Referring to the disputed accuracy of the photographs of the “grotto” at Cheriton Mill, in the Tichborne trial, to which we referred in our last, Mr. Guildford Onslow, M.P., writes to a daily contemporary and says:—“I beg to say I requested that eminent photographer, Mr. Wyatt, of Fareham, to take me certain photographs which were produced in court, and which were perfectly correct and accurate at the time he took them, since which the place is completely altered, owing to sheep

having been peened, as I saw them, all over it, so as to transform what was then a jungle into what is now a desert. In short, the place is now as much like what it was in July as a fox-covert is to Stonehenge." Mr. Wyatt's name is well known as a skilful photographer, who would not be likely to bungle his work; but the present tenant of the place a Mr. Stratton, writes to the *Times* and utterly denies that any change has taken place. The question will then arise, were the photographs "cooked," and how?

**CUSSON'S PHOTOGRAPHIC ALMANAC.**—We have received from Mr. D. H. Cusson's, of Southport, a copy of his "Photographer's Pocket Almanac and Reminder for 1873." As on former occasions, it is a useful and handy little calendar and memorandum book for the waistcoat pocket or for the pocket-book.

**PHOTOGRAPHERS' ACCOUNT KEEPING.**—We have received a sample sheet of Mr. George Hooper's system of Book-keeping for Photographers. As we have before said, the plan is carefully devised and systematic, and will prove a valuable aid in an often neglected department of the photographic business.

**PHOTOGRAPHIC MATERIALS.**—We have received from Messrs. Payne and Chapman, of Manchester, a very complete catalogue of the apparatus and materials they are prepared to supply to photographers.

### To Correspondents.

**THOMAS BAYNTON.**—A suitable etching ground for producing an etched negative on a glass plate might be produced, we should think, by the use of a black varnish. Possibly Bates' black varnish, used as sold, or diluted with turpentine, would answer. Brunswick black, dissolved in turpentine, with the addition of a few drops of castor oil to prevent the film becoming too brittle, might answer. We have seen very good results produced by using a very powdery collodion, sensitizing in the silver bath as usual, exposing to diffused light, then developing and fixing. If a tough, horny collodion be employed, the film tears instead of giving a clean line under the point of the etching needle.

**ONE IN A FIX.**—The presence of small defects in the magnesium ribbon has a tendency to produce the trouble you describe, an unsteady light and occasional stoppage in the combustion. A fresh supply of the ribbon will probably prove a remedy. The light will also go out if the clock-work arrangement fail to push forward the ribbon duly.

**SCOTTICON.**—You will find many formulæ in our back volumes and YEAR-BOOKS. A very good process, yielding fine results, is given on page 118 of our YEAR-BOOK for 1873. Here is another:—Take iodide of potassium six grains, bromide of potassium two grains, and chloride of sodium one grain, and dissolve in an ounce of water. The addition of one grain of gelatine to each two or three ounces of solution will keep the image better on the surface. Sensitize on a fifty-grain silver bath containing twenty minims of acetic acid to each ounce. Develop either with pyro and acetic acid, or with gallic acid.

**J. S. H. (Clapham).**—An "aceto-nitrate bath" was a familiar thing to dry-plate workers a few years ago, when the collodion-albumen process was commonly worked. Its formulæ varied, but the following was a common one:—Nitrate of silver forty grains, acetic acid thirty minims, water one ounce. Your bath, as you will see, had insufficient acetic acid. We regret that we have not time to answer photographic questions by post.

**ENLARGED NEGATIVE.**—We cannot undertake to pronounce definitely which is the best mode of producing a transparency from which to obtain an enlarged negative. You must read what has been published, examine results, and decide for yourself. It is no new doctrine, as you seem to fancy, that so much depends upon the transparency, and that it should be much over-exposed. In our YEAR-BOOK for 1863, upwards of eleven years ago, in describing the production of enlarged negatives, we said:—"On the perfectness of the transparency the result largely depends. It should be very full of detail, and apparently much over-exposed, according to the usual standard of transparencies for the stereoscope." One chief cause of the improved quality of modern enlargements is the greater attention which has been given to the subject, and another the practice of retouching at some stage of the process.

**ANTOINETTE.**—You will find a good method of giving a grain to a photograph in Mr. Croughdon's recent paper before the South London Photographic Society, which we published a few weeks ago. 2. Permanganate of potash is, we believe, occasionally prescribed in weak solution as a wash to sores and ulcers. It will have a cleansing influence, aiding in the removal of putrid discharges. 3. Permanganate of potash used in solution (say five grains to the ounce) applied to a carbon transparency will increase its density. Such transparencies may be tinted.

**R. H. (Swansea).**—As you state the matter, you have a good case against the manufacturers sending out the copies of your photograph. The simplest mode of proceeding is by summons before a magistrate, who can exercise summary jurisdiction, and you can, on proving your claim, recover penalties on each copy issued, not exceeding ten pounds. The *Fine Art Copyright Act*, issued in 1862, contains full details. You had better, however, take the advice of a solicitor. You can obtain permission to examine the Registrar's books at Stationers' Hall on payment of one shilling, and can obtain such a copy of the registration as will be received as evidence in a court of law on payment of five shillings.

**G. W. R.**—We cannot tell of whom a large lens may be borrowed, unless you have some friend who can lend it. We do not know of any one who makes a business of lending apparatus. Some years ago some letters were published suggesting the advantages to photographers if some one would establish a lending agency, but nothing came of it. 2. Some ten or a dozen years ago we described the mode of examining non-actinic glass by means of the spectroscope, and for some years kept up the practice of so examining samples for our readers. The common prism must, of course, be made into a spectroscope. Any one handy in such manufactures could make a spectroscope very cheaply; but not an unpractised hand.

**IGNORAMUS.**—You will find the form of studio to which Mr. Fry refers described, with diagram, in Mr. Slingsby's article in our YEAR-BOOK for 1871. Hot development is only recommended for use in very cold weather. We hope shortly to publish a further communication from Mr. Fry on the subject of rapidity.

**A. G. W.**—You should have stated how and by what formula you prepared your toning bath. Merely stating that you follow Hardwich is insufficient, as he gave various formulæ. The dark pink colouration of your prints is due to a general reduction of the gold all over the print. This may be due to a variety of causes.

It may be the result of using an unsuitable formula; it may be, and very probably is, due to toning in daylight; it may be due to excess of nitrate of silver soaked into the paper upon which the portraits are printed; it may be due to touching the toning bath with fingers contaminated with some other chemicals. Some of the prints, No. 5 being a notable example, are not perfectly fixed, the brown, mottled staining being due to that cause. Imperfect fixation arises from the use of a fixing bath too weak, or exhausted, or from too short immersion, or from the prints sticking together. A good toning bath may be made by dissolving one grain of chloride of gold and thirty grains of acetate of soda in six ounces of water. It should stand a day or two after mixing before use. The fixing bath should consist of four ounces of hyposulphite of soda in a pint of water. It should not be used at a temperature under 60° Fahr., and should only be used for one batch of prints.

**W. PERRY.**—The alteration in the address on the envelope you enclose was made in our office. 2. The matter entirely depends on the nature of the bargain. If the "right to publish" has been definitely sold, of course it cannot be sold again to second person. The power to sell to other people will entirely depend on the terms of the first bargain. 3. Copyright in a picture continues during the life of the author, and for seven years after his death.

**J. GRIFFITHS.**—There is a very good method described on page 70 of our YEAR-BOOK for 1870.

**ANOTHER MEMBER OF THE PHOTOGRAPHIC SOCIETY** writes a long letter regarding the Photographic Society. He especially asks why, if, as has been alleged, there is wide-spread dissatisfaction, was its expression confined, at the last full meeting, to two or three persons, who have the credit of being its originators. He proceeds to comment on what he regards as the "absurd position" of Mr. Stillman in disputing the correctness of minutes of which he knew, personally, nothing. Our correspondent's letter is a long one, and our pages are much too full of this unimportant agitation. Our correspondent's question as to whether all those signing the requisition were really members of the Society, and whether some of those who were members were not technically disqualified, should not be put to us, but to the President at the meeting.

**G. R.**—The loose fog, which may be removed by the fingers, may be due to various causes. It is very frequently due to the use of a newly mixed developer, which, after keeping a few days, will work cleaner. It is due at times to insufficient restraining acid in the developer, and sometimes to impurity in the acetic acid employed. If the acetic acid be pure, increasing the proportion will generally stop the fog; or try the addition of thirty grains of sugar to the ounce.

**DEAF AND DUMB ARTIST.**—Thanks; we shall give details in our next, and also refer to your former communications.

**LARGE PHOTOGRAPHS.**—Mr. Aldridge's communication on this subject, together with several other letters and articles in type, are compelled, by the pressure in our space, to stand over till next week.

Several Correspondents in our next.

The Photographic News, January 30, 1874.

KRONE'S DRY PROCESS.

DR. HERMANN KRONE, the President of the Dresden Photographic Society and editor of the *Helios*, has for some time past paid considerable attention to the matter of dry processes, with a view of considering their adoption in astronomical work, and especially on the occasion of the approaching transit of Venus.\* Dr. Krone has now been selected by the German Government to undertake the photographic arrangements of the German expedition to be despatched to the Auckland Islands (south of New Zealand) in June next. The appointment is one upon which we sincerely congratulate our learned colleague, for it is a post for which he is especially fitted, being both a practical and scientific photographer. During his absence, the journal which he has founded and edited since its birth will be discontinued; but we hope that photographers will still have the benefit of his experiences during his temporary sojourn abroad conveyed to them through some other medium. In the last number of *Helios* we find a description of a new dry process by its editor, and as this will doubtless be the method he intends to employ in the Southern Ocean, our readers cannot fail to be interested in it.

The method permits the preparation in advance of any number of plates, which may be preserved in a damp climate, and are perfectly insensitive to light of a certain degree of intensity. The sensitizing and washing of the films may be fulfilled in a few minutes, and may, should necessity compel such a course, be manipulated by operators little skilled in the business. If desired, however, the plates may be prepared at once from beginning to end, and then require less time and less care, less silver and less rinsing water, than are necessary in practising the collodio-albumen method. The dry plates, prepared either at one time or at two separate operations, are as sensitive, and yield as sharply-defined negatives, as any collodio-albumen plates, while the mechanical stability of the film is not inferior. At the same time, they may be employed just as well in a moist atmosphere as in a hot dry temperature, remaining clean and sensitive for a long time, and not liable, as in the case of the above-mentioned plates, to undergo spontaneous decomposition by the formation of sulphide of silver. The method, moreover, possesses the great advantage that the solutions and baths employed are not in any way changed by continued employment, thus jeopardizing the certainty of the results; whilst in the collodio-albumen method, not only the collodion and the silver bath, but also the albumen, and especially the second sensitizing solution, after it has been employed once, are for ever altering, so that repeated testing of the same is required. The last named silver solution must, indeed, always be applied fresh. In my recent method, however, the solutions and baths, if only carefully carried, will remain good on a journey for years, and may be employed to the last drop. With some little practice, too, the process yields constantly good results.

I now proceed to give practical details of the method, more especially in relation to its adaptation to the Transit of Venus Expedition. The following are the component parts of the process:—

a. *Silver Alcohol*.—A test tube is obtained, together with the following ingredients:—

Nitrate of silver	...	...	10 grammes
Distilled water	...	...	10 "
Absolute alcohol	...	...	250 cub. cents.
Nitric acid	...	...	5 drops

The nitrate of silver is put into the test-tube, and the distilled water added; by gently heating a solution of the silver is brought about, and this is then gently added by degrees and during agitation to the absolute alcohol; the test-tube

is rinsed out with a little of the alcohol, so that none of the silver shall remain behind, and, finally, the five drops of nitric acid are added. This solution is termed silver alcohol, and it does not need filtration.

b. *Normal Collodion*.—This is made up of—

Alcohol (nearly absolute)	...	1 litre
Pyroxilin	...	60 to 70 grammes
	(according to solubility)	
Ether	...	1 litre.

The mixture is allowed to stand, and then the upper and clearer portion decanted for use. This collodion is about double the thickness of the ordinary material.

c. *Silver Collodion*.—This is prepared according to the undermentioned formula:—

Normal collodion	...	250 cub. cents.
Silver collodion	...	125 "
Ether	...	125 "

If this collodion prove to be too thick, it is diluted to any desirable extent with a mixture of alcohol and ether kept ready for the purpose.

c. 1 solution is made up of—

Silver alcohol	...	124 cub. cents.
Absolute alcohol	...	125 "
Ether	...	250 "

The collodion, when ready for use, must neither be too thick nor too thin, and when the consistence has been approved of by means of a trial plate, there are added four to six drops of negative varnish for every ten cubic centimetres of silver collodion. The varnish of Schering, of Berlin, as also that of Professor Vogel, is very suitable for the purpose.

d. *Negative Varnish* is thus constituted:—

White shellac	...	3 parts
Sandrac	...	3 "
Alcohol (at 95 deg.)	...	40 "

The silver collodion, if well stoppered and kept in the dark, may be preserved for years, although after a time it assumes a light brownish tint. It may be poured with the same ease as iodized collodion. No preliminary coating is required in the preparation of plates by this method, for blisters or raising of the film are things unknown. The well-cleaned and polished glass plates are simply coated with collodion, and then put into a dipping bath of a vertical or horizontal nature, containing the undermentioned solution, viz:—

e. *Iodide of Potassium Bath*.—This is made up of—

Iodide of potassium	...	20 grammes
Bromide of potassium	...	20 "
Distilled water	...	1 litre
Silver collodion containing varnish	...	5 drops

The iodide and bromide are dissolved in the distilled water, and the five drops of silver collodion are then added. The solution is well shaken for a few minutes, and then filtered through filter-paper. To remove any trace of hyposulphite of soda from the latter, it should be first washed in several changes of water, and subsequently twice rinsed with distilled water. (To be continued.)

“THE PENCIL OF NATURE.”

BY A. BROTHES, F.R.A.S.\*

Our Secretary has announced that I purpose this evening to read a paper on the “Pencil of Nature.” I intend merely to call your attention to the present condition of some prints in Nos. I. and III. of that work, and to make some general remarks on the fading of photographs.

It has often occurred to me that one of the reasons why so few papers are read before our Society is that members hesitate to undertake the writing of a formal paper. It is much easier to come to the meetings prepared to speak on a certain subject than to sit down to the task of writing. A short address would, in most cases, answer the purpose of introducing a subject for discussion; and it is this

\* See article by Dr. Krone on “Stable Photographic Films,” PHOTOGRAPHIC NEWS, 7th March, 1873.

\* Read before the Manchester Photographic Society.

which makes our meetings useful and interesting, and there is no trouble of, possibly, a tedious preparation. A little previous thought, and a few examples for illustration, are alone necessary. The announcement of a subject for discussion has a marked influence on the attendance of members, and I am glad to be able to say that for our next two meetings papers or addresses are promised.

We have all heard of the instability of ordinary photographs on paper: and if we did not know it from experience, we are constantly reminded of the fact by writers in the various newspapers and periodicals. If those who write understood their subject, and refrained from making sweeping assertions, I, for one, would not complain. But I contend for the stability of photographs, and complain that imperfectly-informed writers do our art serious injustice. Take the following as an illustration. It is from the *Lithographer*, No. 42. The writer, in an article on "The Correlation of Photography, Lithography, and Typography," says, respecting photographs:—

"There are few persons who have not suffered from the disappointment occasioned by the ephemeral character of the ordinary photograph. The portrait of a child, a sister, a parent, or a wife, has been treasured, perhaps, for years, and its owner has had the pleasing impression that in the picture the loved, but lost, one lives again. The view of a noble landscape, seen, perhaps, under circumstances that can never recur, has remained in our favourite album, and the happy anticipation indulged in that in some quiet hour we may, in fancy, once more visit the scene. Alas! when brought to the light our pictures are gone. The lineaments of the cherished features, the lights and shade of the landscape, are all blurred and blotted out, and there is little before us but a confused series of shades of brown, pink, and yellow.

"We have by our side a copy of the *Photographie Art Journal*, published in 1858. One cannot help smiling at the seedy and sickly appearance of the good people who once adorned its pages, and the landscapes fading into that distance which assuredly does not, in their case, lend any kind of enchantment to the view. Dr. Trench, Dr. W. Russell, Miss Nightingale, and Samuel Lover, are or were all there, whilst Windsor Castle and Stoke Pogis have got into a London fog. The editor well says in his preface that, as a graphic art, the strongest recommendation of photography is fidelity—a truthfulness impossible to the productions of the other graphic arts; but if he could have added durability to fidelity, he would have been able to write in a far different strain from what appears in his closely-printed pages.

"This non-permanency is the great defect of the photograph, and it almost outweighs all its other advantages—even the absolute accuracy to nature which it presents, and the ease and simplicity with which the picture has been obtained. What still further aggravates the matter is, that this fleeting character is probably inherent in the ordinary photograph; for the very action of light which forms the image tends to destroy it—even as our life is gradually exhausted by the very means we adopt to preserve it."

Now it cannot be denied that some photographs do fade; so do water-colour drawings. Some oil paintings change colour (who does not remember the "Strawberry Girl?"), and even become almost valueless. But would the newspaper and periodical writers make the same charge of want of stability of water or oil colours because some have faded? I have generally noticed that ordinary photographs are called "ephemeral" when something is to be described which is supposed to be permanent, and that will be seen to be the case in the article from which the above question is taken.

I have here, perhaps, the best example of a faded photograph which you have ever seen. It is stamped on the back "Patent Talbotype, or Sun Picture," and in ink is written "The Boulevards, Paris." Without these marks it would be very difficult to know what was once on the paper. The print was issued in the "Pencil of Nature," in 1844. Fortunately I have here another print from the same negative, printed in the same year, and apparently in the same condition now as it was nearly thirty years ago. I have also here other examples from the same work—some faded and others perfect.

Can this want of stability in some cases, and permanence

in others, be explained? I think the cause is obvious. The print of "The Boulevards—now almost white paper—has evidently been fastened to the mounting-board with some substance which has injuriously affected the print. The other print of the same subject is not attached to the eard, excepting for about a quarter of an inch around the edges, and this quarter of an inch of the photograph, you will notice, is as completely faded as the other example. Can further proof be wanting that the mounting material has caused the mischief? It would be valuable and interesting if the history of these two prints could be made known. Was gum or paste used? and why were some of the prints firmly attached to the eard, while others were fastened at the edges only? I wish it to be noticed that my remarks refer to all the prints I now produce. The four fastened to the mounts are badly faded; all the rest are in good condition.

I am aware that this subject has often engaged the attention of photographers, and is surrounded by many difficulties. It is certainly very mysterious why some prints fade and others do not. I have just selected from our portfolio a print of Haddon Hall. It was printed on January 5th, 1855, for a special purpose, and was submitted to the council of this society on the evening of the day named. The print was toned in the old hypo. and gold bath, and was merely rinsed in water and then mounted with gelatine. It is on plain paper. I wrote on the back of the print, "Not washed," adding the date, and it has remained in the portfolio until this evening. I will endeavour to show you its present condition by means of the magnesium light, and you will see that it appears to be in the same condition as when first printed. There is a small yellow mark, but that was done when I last saw the print, about fifteen years since.

I have also selected from the portfolio two other prints done in 1855. One is the portrait of Mr. (now Sir William) Fairbairn, and a copy of an oil painting. These appear to be unchanged. I have to thank Mr. Lund for bringing two prints of the same subjects, and those seem to be unchanged also. It has to be borne in mind that all prints are not printed to the same depth. Some are lighter than others, and when placed beside the darker ones appear to be changed when they are not. Our President says his print of Sir W. Fairbairn faded. Perhaps it was not taken care of. I do not say that my prints are less liable to fade than others; but I do contend that if every care be taken in the preparation and mounting of photographs, and they are then as carefully preserved as water-colour drawings, we have nothing to complain of as to their permanency. As a rule, photographs are not taken care of, and in this is to be found one explanation of their fading.

It is often said that a photograph has faded when the paper only has changed colour. Here is an example in a group of three figures—a gentleman and two little boys. One of them, then about seven years old, is now a member of our council—evidence of the age of the print. It will be seen that the half-tones in this print are good, but the paper appears somewhat yellow. It will be remembered that this yellowness of prints was frequently the effect of the old system of toning. Here are examples which the magnesium light will show you to be perfect in every respect, excepting the colour of the paper.

Much of the discredit under which photographers have fallen arises from cheapness and carelessness. Look through any friend's album, and the probability is that all the "seedy" prints have been done during some sea-side visit, or have emanated from some of those places of business noted for cheapness rather than quality. Not many months since I was examining a celebrated book of travels, containing the portrait of the author of the book. This book had not been published three months, and yet the portrait was fading. The work was sold in thousands, and there can be no doubt, I think, that cheapness had something to do with the faded print.

APPENDIX TO THE PAPER ON THE MANUFACTURE OF LIMES FOR THE LANTERN.

BY M. NOTON.\*

THE inferiority of the light I had here at our last meeting, compared with the good one frequently obtained at home, has compelled me to come before you again this evening to explain what I believe to be the reason, and to give you an account of the remedies I have adopted to overcome the defect.

The primary cause was a deficiency of pressure of the coal gas. Secondly, I had ten feet of india-rubber tubing from the chandelier to the lantern, six feet of which were wired, and this retarded the flow of the gas very much; so between the two I had an insufficient pressure to enable me to give you the amount of light you were led to expect.

When the oxygen was turned on the hydrogen was driven back, and it required the greatest nicety of adjustment of the oxygen tap to get a proper proportion of the two gases. The blowpipe or burner I used mixes the two gases just before issuing, and requires more pressure than those with the oxygen inside the hydrogen flame.

I thought I should have to use the latter form of burner in future, where probably there would be a diminished pressure of coal gas, and was about to fit to the lantern a good one I have, when it occurred to me to make and try a jet of larger bore. I made one about double the area of orifice. The two jets are on the table—the smaller-bore one being tipped with platinum, the other all brass.

I think it fortunate that I should be baffled as I was, for it has put me in possession of a remedy I had not before thought of. Instead of having only one jet, I shall be now armed with two or three of different bores in future, the same as when you go out with lenses of different foci to your cameras. Instead of the india-rubber tubing I had last time from the chandelier to the lantern, a copper pipe is now attached, and a pressure gauge is also applied, so that we may see what pressure we have to work with.

The next thing I have to mention is the lime cylinder. I have always been an advocate for the disc, but the cylinder is more convenient to make.

As an improvement I have, since our last meeting, made a small semicircular trough to hold the cylinder when laid horizontal, or in a line with the axis of the lenses, instead of vertical, the flame being applied to one of the flat ends of the lime cylinder (the hardest part) instead of about the middle of the side when vertical (the softest part)—another very simple matter. I consider this a very important improvement, for the following reasons:—

Supposing a solid cylinder to be only one and a-half inch long by five-eighths of an inch diameter, we at once convert it (by laying it down) into a disc one and a-half inch thick by five-eighths of an inch diameter, both ends being usable; we thus get a miniature sun of that diameter tolerably well defined. This being so satisfactory to me, I have ground down and re-made most of my lime cylinders over again, solid. No more drilling will be required now, nor any more vertical cylinders for the future.

I think a five-eighths better than a fourteen-eighths disc, because the whole of the smaller one is incandescent, and there will be more economy in the materials; also, the trough is a much easier thing to make than the disc-holder.

If the end of the lime cylinder does pit some, it can only be a good half-inch in diameter, and, if it becomes very deep, the other end is available immediately by turning the lime end for end; then, again, the two ends can be pared off, and you have a new lime surface to go on with. About three-eighths of an inch in depth is calcined at a time, so that a cylinder may be used about four times.

The curved surface of the vertical cylinder does not give off the greatest amount of light until it has become pitted to some extent, which is really an improvement as far as

that goes; but it appears to me that a flat surface at the beginning is the best under all circumstances.

PHOTOGRAPHIC ILLUSTRATIONS OF THE ERUPTION OF VESUVIUS OF APRIL, 1872,

Collected and Prepared by J. M. BLACK, Esq., J.P.:

Explanatory Remarks.

BY DR. MANN.\*

In order that the several incidents of these pictures of volcanic destruction and devastation may be properly apprehended, it may be as well briefly to state what occurs when a stream of molten lava breaks out from one of the high slopes of Vesuvius at the time of an eruption. First, the lava runs down the steep side of the cone with a rapid descent for 800 or 1,000 feet, but not with the noise and splash that attend a sudden fall of water. It glides down on its fiery path with a quiet, stealthy, serpent-like movement, on account of its thick, pasty consistence, lapping round all objects that it encounters by the way. On reaching the gentler declivities around the base of the cone it slackens its speed, soon moving not faster than a man can easily walk, and even at a less rate than that towards the side, where a solidifying crust first begins to form. It soon melts out for itself a regular channel in the old ashes and lava, with banks rising some feet above the surface of the burning stream. As it gets further and further away from its source it spreads wider and wider, and moves more and more sluggishly, until at length it stops altogether in front, forming a massive rampart many tons in weight, with firm, hardened sides, due to the cooling crust, but with streaks of liquid fire still seen shining through here and there. The rampart grows bigger and thicker, until at last, with a tremendous crash, it rolls over, pushed out of the way by the pressure of the stream gathering behind, and then a new rampart begins to form; and this process is repeated again and again, until the *vis a tergo* of the flowing lava has been exhausted. From the influence of this process, and from the subsequent operation of air, the beds of old lava assume the appearance which has been well compared to that of a suddenly petrified sea, with waves twelve or fifteen feet high changed into stone, but with their sloping faces encumbered with loose clinkers that break away and roll down into the hollows of the undulations at the slightest touch. All the old lava lying between the Observatory and the base of the cone of Vesuvius is of this broken, billowy, clinker-encumbered character. Four photographs of the series are given to illustrate this peculiarity, and they do so very completely and beautifully. They were taken from the old lava of the eruption of 1858, below the Hermitage Hill, and very adequately represent the contorted and ropy structure of the rock. One of this series also shows the position of the Observatory in relation to these lava-deposits after the eruption of 1858.

One of the photographs represents the appearance of the eruptive fissure of 1861, on the south-west side of the mountain, near Torre del Greco. The fissure was 2,000 yard

\* A communication to the Manchester Photographic Society.

\* Continued from page 39.

long; and in this eruption there were eleven craterlets vomiting ashes; but only one emitted any lava, and that in small quantities.

Three of the photographs give the form and appearance of the terminal crater on the summit of the cone ten days after the commencement of the eruption of 1872, and when all eruptive action had ceased. The first of these pictures of the great crater shows the aspect of the cone as it appeared from a mound of ashes situated in the fissure opened out on the Atrio del Cavallo. Several small fumaroles still emitted sulphurous-acid and hydrochloric-acid vapours on this mound; and its surface was incrustated with chloride of iron. In this photograph the cliffs of Monte Somma are seen to the left; and in the centre is shown the great rent, extending through one side of the cone in a north and south direction, from the summit to its base, and some distance into the Atrio del Cavallo in front. Another and a larger photograph shows the interior of the crater, with the inner view of the same great rent. Bold masses of projecting rocks are seen descending into the abyss. The rounded and peaked eminences on the further rim of the crater were both active craterlets before the eruption. The ragged dark mass of lava on the right was coated brilliantly with sulphur and chlorides of iron and sodium. The front rim is formed of three distinct terraces; and upon the slope of one of these, inclined at an angle of about 30 degrees, rests a large volcanic bomb. The third view of the crater also represents its interior, and shows the appearance of two curious rocky projections which advanced towards each other from either side, like partition-walls. These joined together about 30 feet further down, and formed an arch below, by means of which the otherwise divided halves of the crater communicated. The walls of the crater here seemed to be almost perpendicular; but the eye could not make out the form of objects below this distinctly, on account of the prevalence of thick vapour. A small cone, however, could be discerned near the bottom, which seemed to be about 30 feet high; and the entire depth of the crater, from the upper rim to this cone, was approximately estimated at 650 feet.

Mr. Black states, in regard to the method by which his own photographs were made, that "some of the negatives were prepared according to Lee's formula for the collodio-bromide process, but that he was unfortunately compelled to use brackish water, and to submit to other unfavourable circumstances during their preparation. He wishes it also to be understood that the Vesuvian views were taken in an atmosphere charged with gases adverse to the sensitiveness and integrity of the plates, and deems it a marvel that the views on the cone were secured in even an imperfect form, as an almost suffocating atmosphere invested the place. The smaller view of the crater is somewhat obscure from this cause. The greater distinctness of the larger view was mainly due to a more favourable direction of the wind at the time when it was taken."

#### PRINTING AND TONING ALBUMEN PAPER.

BY R. M. CRESSEY.\*

ONE of the chief difficulties met with in photography, at the present day, is the want of less-complicated formulae and more care and skill. By adopting the following plan you will be enabled to produce as fine results as one could wish, with the least difficulty.

Procure any good sample of paper, and prepare a silver solution as follows:—Dissolve in ice-water sixty grains of silver to each ounce of water used. To every thirty-two ounces of solution add twenty drops of a saturated solution of alum in water, and add these to four drachms of a saturated solution of sal soda in water; shake well and filter, and float your paper from one minute to three, and if for immediate use, dry by artificial heat, and fume over strong ammonia ten to thirty minutes. When surface-dry, place between blotting-paper, previously prepared by drawing through a twenty-five grain solution of sal soda in water. When dry make into hook-form, and place the

\* Philadelphia Photographer.

silvered paper between the leaves. Paper thus prepared will remain good for months, and when about to use, fume ten to thirty minutes. Print but a very little darker than you wish the finished print. Trim, wash in three changes of soft water, and tone in the following:—Soft water, thirty-two ounces, fine table-salt, one tablespoonful. In a graduate put one to two drachms of acid gold solution, and a small piece of blue litmus paper. Now add saturated solution of sal soda in water, drop by drop, till the litmus-paper remains blue, and add to the above toning solution. Now place a few prints in, face down; at first they will turn a bright cherry colour, and soon to a brown-sepia, or steel tint. Fix in hypo: strength one to ten of water, with a little salt. Turn the prints continually till thoroughly fixed, with the face down. Take directly from the hypo, and place in a strong solution of salt and water ten or fifteen minutes, and add fresh water, and handle the prints in several changes of water one-half to three-quarters of an hour; then pile the prints, one over the other, on a piece of glass, and press out the excess of water, and immediately mount.

By following the above plan, you will not be troubled with any blistered prints, and they will retain all their original lustre.

*Acid Gold Solution.*—Take four parts muriatic acid and two parts nitric acid; take gold coin and roll thin, or cut in small pieces. Place in a small glass flask, or an evaporating dish, over a sand-bath, and apply gentle heat. After adding a sufficient quantity of the prepared acid to cut the gold, then cool off, and add water (if you used a two and a-half dollar piece) twenty ounces. Filter and bottle for use.

#### ON THE CAUSE AND CURE OF BLISTERS IN ALBUMENIZED PAPER.

BY DR. J. SCHNAUSS.\*

THE introduction of the gold toning bath dates almost from the universal adoption of albumenized paper. At the same time a peculiar defect crept into the printing process, which attained its highest point with the employment of very brilliant albumenized paper—we mean the production of blisters in the albumen surface of a greater or lesser dimension, which only become visible in the toning bath or in the washing trough.

The opinions of those practical and learned in the matter, upon the appearance of this phenomenon and its cures, are as numerous as they are different, and we will here cite some of the most interesting views expressed, to show how they agree. M. Haugk says that blisters are produced upon papers albumenized in hot weather, and which are therefore too dry, for if a moist paper is albumenized it develops no blisters. In America they employ ether added to the silver bath to prevent the formation of blisters, while Dr. Liesegang recommended some time ago a prolonged floating upon the silver bath.

Upon the strength of the silver solution, photographers are not in accord: some recommend a weaker and others a stronger solution to prevent blistering. M. Carey Lea tells us to employ a weak soda bath between the operations of fixing and washing. Mr. Henderson seeks the cause of the defect in the strong sizing of the unprepared paper, the albumen being, in such a case, unable to penetrate into the material. He recommended the keeping of albumenized paper in a moist locality, and to employ a weaker silver bath. Mr. Dummore advises dipping the albumenized paper, after sensitizing, in strong alcohol; while Mr. Spencer avows that if an acid toning bath is made use of, blisters need not be feared.

On the following points all are agreed: the blisters are to be found only on highly albumenized papers; nevertheless, the defect is not universal, for in a quire of paper only certain sheets exhibit the defect; moreover, sheets following one another, which may be presumed to be albumenized in order, often, as we have observed, show the defect.

Alkaline baths (as also ammonia fuming) favour the

\* Photographisches Archiv

formation of blisters, a fact that may be explained by the solvent action of alkalis upon albumen.

All substances which coagulate albumen are capital remedies against blisters, as, for instance, alcohol and ether, and likewise heat. Nitrate of silver can scarcely be classed among these substances, as it only coagulates by combining with the albumen, forming albuminate of silver, which is insoluble in water. As we know, however, the nitrate only partially changes the albumen, for while the surface is rendered insoluble, the film underneath, next the paper, still retains its solubility, in which the cause of blistering may be sought. If an albumenized paper of this kind is floated for a few moments on the back, no blistering need then be feared. This method is, however, too costly a one in practice, for if this extra amount of silver solution is not actually lost, still it is at any rate absorbed from the bath. Moreover, this is a remedy of which the manufacturer of the paper cannot avail himself, any more than the coagulation of the film with alcohol, &c. We shall, however, at the end of this article specify a much more simple and certain remedy, which may be employed with advantage both by manufacturer and customer.

A perfectly analogous appearance may be observed in the Taupenot colloid-albumen process, for very often the albumen rises in blisters during the operation of fixing with concentrated soda solution, a strong fixing solution bringing out the defect in a much more marked degree than a dilute one.

On drying, the blisters always disappear—so completely indeed, that many photographers trouble themselves little in the matter; often, however, in the dark shadows, they leave behind grey spots or patches. Moreover, the lifting of the film affords convenient recesses for the soda solution, which accumulates there, and subsequently forms stains, as it cannot easily be displaced from those spots by subsequent washing.

As I was of opinion that the formation of blisters was due to a partial running off of the albumen film from the paper, the cause of which was possibly different, and at present unknown, I instituted the following control experiments on the subject:—

1. From a sheet of brilliant albumenized paper, which was proved to be inclined to blister, some small pieces were cut, of which a few were sensitized in the ordinary manner, except that the back was also floated on the solution for a few seconds. The result was that no blisters were formed (after fixing and washing), but, at the same time, many iron spots were apparent, and its sensitiveness impaired, as well as the tone of the pictures injured, there being some patches of a red tint which were difficult to tone.

It was quite immaterial whether the paper was exposed to light or not, the blisters appearing just as frequently upon the whites of the pictures as upon the printed portions, so that the effect of the light can have nothing to do with the formation of the blisters.

2. Other pieces from the same sheet of paper were coated on both sides with alcohol, dried, and sensitized. No blisters were produced; aqueous solutions were easily repelled by the albumen surface, as a proof of its complete coagulation. But light red spots were apparent in this instance also, a proof of unequal toning. In this case, too, the sensitiveness seemed diminished.

3. Other similar bits of paper coated with alcohol on the face only behaved in the same manner.

4. The same result was obtained with paper which, after sensitizing, was treated with alcohol on the back.

5. The same result was also obtained by the addition of alcohol or ether to the silver bath; these additions would doubtless influence both the keeping qualities and character of the silver bath.

All these remedies have the disadvantage that they cannot be employed by the manufacturer, but only by the consumer, which cannot be said of the method I am about to refer to, and which I have several times tested as to its efficiency.

I must here repeat that in the first plan it seemed to me

proven that the formation of blisters in the albumen film consisted in the unequal coagulation of the albumen; or, in other words, in the partial adhesion of it to the surface of the paper. If, as happens in many factories, the paper is, before being albumenized, coated with a solution of india-rubber and benzole, as a matter of course the blisters become more frequent, supposing the albumen is applied undiluted, and foras, therefore, a very thick and tough skin.

A perfect coagulation of the albumen is nevertheless in no way profitable, as this prevents the uniform absorption of the bath solution. If we take into consideration the favourable influence of moisture during the keeping of the paper, or just prior to its being sensitized, as a means of preventing blistering, we must come to the conclusion that the best plan is to bring the albumen into a more soluble state, not from the front, however, which would dissolve off if brought into contact with water, but from the back through the surface of the paper. In this way a perfectly firm adhesion of the albumen film to the paper is brought about. The manufacturers will be able to say better than I whether they moisten their paper or not before albumenizing; but when they do, further moistening of the film subsequently would be necessary. How far, too, a very dry or warm storage would necessitate moistening again on the back can only be decided by experience.

I must not also forget my observation that those albumenized papers which smell very foul are less apt to blister. It is not impossible that by becoming rotten, so that several gases are disengaged, the albumen becomes more loosely attached to the paper. It is a well-known fact that many manufacturers purposely allow the albumen to become rotten before it is used, as it then becomes more fluid. At first I allowed the albumenized paper to float on water on its back until it had become flat, small pieces always rolling up very rigidly; but I found that the paper absorbed too much water, and for this reason I preferred to lay the sheets face downwards on clean blotting-paper, and to sponge the back with a very moist and perfectly clean sponge. Before being sensitized the paper must be again rendered pretty dry (being dried in the air, and not by artificial warmth), as otherwise the surface will be unequally moist, and red patches on the finished photograph will be the result.

That photographers are more or less troubled with blisters is due doubtless to the greater or less degree of moisture in the store where the albumenized paper is kept, as also upon the strength of the soda bath employed. Is there, for instance, any tendency in paper to become blistered, this is scarcely apparent in a weak soda bath, whereas long-continued immersion in a strong hyposulphite solution develops blisters in plenty. The first cause, viz., the changing amount of moisture in the atmosphere, may also influence the albumenized paper during manufacture. In the absence, however, of any definite knowledge as to the mode adopted in the manufacture of a paper, which no doubt differs in many establishments, the primary cause of the defect can scarcely be fixed.

If, before employing a fresh batch of albumenized paper, it is desired to discover which sheets will blister, and which will not develop the defect, it is well to cut some small strips off several of the sheets, and, having numbered them for identification and comparison, they should be tested. They are floated (not immersed, for this would have the effect of preventing blisters) upon the silver bath, and are then treated in the same baths exactly as if they were pictures, only a rather stronger hyposulphite bath should be employed than usual. When in this latter solution, or in the washing bath following, the paper may be examined for blisters. These manipulations may all be carried out in a very short space of time. Such an examination as this will show that in one and the same quire there are sheets that blister, and others which do not, while some sheets will be found liable to blister at one end and not at the other, the reason for this being, no doubt, that in drying, the albumen has run to one side, where a thicker film has been produced.

## THE PHOTOGRAPHIC SOCIETY.

The Council of the Photographic Society, acting in accordance with a requisition forwarded to them, have appointed a special meeting of the members to consider certain amendments in the laws proposed by the requisitionists. In order to avoid the inconvenience which might arise to many members in being called upon to attend two business meetings within a few days of each other, the special meeting has been called for the same evening as the annual meeting, the precedence being given to the former, which will be held at half-past six in the evening, and the ordinary annual meeting at eight o'clock, as usual. The amended laws, v. and vii., proposed by the gentlemen signing the requisition, have for their intention, it will be seen, a more popular form of electing the officers of the society. It would be possible, we think, and with advantage, to make the operation of the rules wider and more representative still, and not only to give all the members more complete control over the elections, but to secure more frequent accessions of "fresh blood" into the council, and more extensive distribution of the duties and honours of office amongst the members. There are, moreover, other rules, besides v. and vii., which are clumsy in construction and obscure in meaning, the revision of which is desirable. The council, in the circular just issued, calling the meeting, instead of offering any amendment expressing antagonism to the wish of the requisitionists, simply suggest the formation of a committee, consisting chiefly of members of the society not connected with the council, for the purpose of revising the rules generally, and reporting to the society at large. By this means the wishes of the society regarding the election of officers may be met, and a code of rules secured which shall not be open, in construction or spirit, to the stigma which has been cast on those by which the society has been governed during the past twenty years.

## SECURING SHORT EXPOSURES.

In some recent observations on the subject of long and short exposures, we mentioned the fact that some portraitists recognized advantages in sittings sufficiently long to allow the features to acquire composure after the first few moments of nervous anxiety which in some cases follow the injunction to remain quiet. There can be no doubt, however, that every facility which enables the portraitist to reduce the duration of sitting at his pleasure must be regarded as a valuable accession of power. In the course of a recent conversation with Mr. J. R. Johnson, he was good enough to detail the results of various observations he had made during a recent visit to Paris and Marseilles, when various photographic novelties came under his attention.

In visiting the studio of M. Wallerie, at Marseilles, whose portraits were amongst the most perfectly lighted he had seen, he was filled with astonishment on entering the glass room. It was in construction, to use his own words, rather like an enlarged cucumber frame than an ordinary photographic studio, the roof was so low and nearly flat. When he witnessed a sitting, he was still more surprised at the extreme rapidity of the exposure, which, in mid-winter, occupied an insignificant number of seconds. The disadvantages of very lofty studios are familiar to most portraitists; but few have ventured on the experiment of making the roof so low that a tall man only just escaped striking it with his head. It is clear that, for many reasons, the nearer the sitter is to the glass the greater the amount of light he will receive, and the more intense that light. Not because, as we have heard the matter thoughtlessly argued, the sitter is nearer the source of light, because the glass roof is not the source of light; it merely represents the aperture through which the light passes, with such loss as it suffers from absorption by the glass. But the nearer the sitter is placed to the aperture through which light passes the greater must be the amount of light from the sky. The problem to be solved in building a glass house is to secure every ray of light which can possibly fall upon the sitter and light him effectively, and to exclude every ray which does not so light him from the studio altogether. If the sitter were placed in an open place, with the light of the sky reaching him from every direction, the opaque parts of the studio should consist of such walls or screens as would exclude all light falling on parts not required, securing the most brilliant illumination with the most effective gradation into shadow possible. If theoretic considerations only prevailed, it would seem that a high skylight, with side lights joining it, should be as effective as a low skylight. As a practical fact, varied experience has shown that a low skylight is, under any circumstances, most conducive to rapidity, and that it generally affords facilities for the most effective lighting. Our object here is not to discuss the question of glass houses generally, but simply to give renewed effect to the limit which our friend's observations has recalled to our attention.

We may remark, in passing, also, that the style of portrait in vogue in the studio in question, and also in Paris generally, is the enamelled cameo cabinet, described by Mr. B. J. Edwards in our YEAR-BOOK. It is certainly a most effective style of portraiture, the enamelled surface and convex cameo form harmonizing admirably with each other, giving an unusually fine effect of brilliancy and relief.

Another of the facilities for reducing exposure has been frequently brought under the attention of photographers, but has failed to secure general consideration. We refer to the accelerating influence of diffused light applied to the sensitive plate. We mention it again here simply to state the result of experiments which had come under the observation of Mr. Johnson when in Marseilles. Our readers have been made familiar, in the letters of M. Lacan, our French correspondent, with the name of M. Melchion, an experimentalist in this direction. In Marseilles Mr. Johnson visited M. Melchion, and was much struck with the unquestionable acceleration obtained by the aid of diffused light. The mode employed by M. Melchion, as our French correspondent has described, is very simple, and recognizes simply the influence of weak white light, discarding any notion of an occult action in coloured light. Before exposing the plate upon the sitter, he submits it for a few moments—two or three being generally sufficient—to light passing through a ground glass. This exposure is sufficient to initiate an action all over the plate where the illuminated image falls, but insufficient to produce reduction where no further light falls, so that no fog need result. If any trace of fog be found to follow, the exposure through ground glass has been too long, and must be reduced. It is precisely the same in principle

as the momentary exposure of the Daguerreotype plate to diffused light, which we have often described, and which twenty years ago we constantly practised. There is another noteworthy point in connection with this operation to which Mr. Johnson called our attention. The result of such exposure to diffused light is not a simple acceleration: it effects something more, especially where the sensitive film consists entirely or largely of bromide of silver. It renders the film sensitive to non-actinic rays, which, in an ordinary exposure, would have been totally without action upon it. Objects of vivid yellow, orange, or red, which in an ordinary exposure would have produced no action upon the plate, are found, after the plate has had this momentary exposure to weak diffused light, to act and produce images in their due gradation of light and shade precisely as objects of actinic colour. This, if it be found confirmed in general practice, is surely an advantage which cannot be overestimated.

The important point is to secure a satisfactory method of regulating the amount of white light, so as to secure sufficient to initiate action, and not enough to induce fog. M. Melehon, as we have said, uses ground glass. His method having been tried and adopted in Paris by several of the most distinguished portraitists, some of them have used opal glass as more convenient. M. Lacan's letter, in our last, mentions some of the gentlemen who have adopted the principle, and describes the ingenious mode in which a disc of ground glass, or opal glass, in the cap of the lens, is made available in securing the brief action of diffused light. Our readers will remember the plan patented by Mr. Gage, a few years ago, of securing a similar end by exposing the plate in the camera for a few seconds to a piece of black cloth or velvet. An exposure to weak diffused light, strictly under control, appears to us better adapted to the end than the use of green or red glass in the camera; but whatever method be employed, we cannot but think that some of them are worthy of more attention than they have yet received, and, if anywhere, surely in the dull, murky light of an English winter.

DEFLUBE'S COMBINATION CAMERA.

A LANDSCAPE camera has recently been devised by M. Deflubé, of Paris, capable of producing upon one plate a combined picture made up of different views. The camera, according to the inventor, not only allows one to pick out suitable objects here and there, such as may be desired to build up an effective picture, but also permits the photographer to produce a picture of large dimensions with a comparatively small lens.

The camera consists of three parts, of which the front carries the lens, and the back the focussing screen, while the middle portion contains a box, in which there are two slides; the one to move from the right, and the other from the left, both fitting in one and the same groove; and only that portion of the view is rendered visible on the focussing screen which it is desired to secure in the composition picture. These slides shut up perfectly, meeting together, but they are both of them as long as the breadth of the camera, so that any portion of the combination may be as small or as large as desired.

The three parts of the camera fit neatly together, so as to be easily formed into a single piece of apparatus. When one exposure has been made by opening one of the slides, the camera is taken to another spot, where another exposure takes place, the second slide being opened this time. To prevent any line showing where the pictures join, the box containing the slides is placed about 0.2 metres from the focussing screen and from the plate. In this way a half-shadow is produced on every opening of a slide, and the light is so diffused that no action whatever is afterwards visible upon the glass of any division between the combination pictures.

The apparatus is, of course, especially suited for employment with dry plates.

BLEACHED SHELLAC.

A METHOD for producing a good white lac appears in the *Hessian Commercial Journal*, which, although not altogether new, deserves to be quoted, because of the difficulty at present existing of getting a material of this description suitable for photographic purposes. That usually obtained in commerce is not of a permanent, unalterable nature, and, moreover, it is, as a rule, of a very brittle character. If chlorine have been used in the bleaching process, and the product contain merely a trace of this element, the same may act injuriously upon any metal with which it comes into contact. So uncertain, indeed, is the nature of bleached lac, that many photographers prefer to employ the native material rather than run the risk of having a treacherous film.

The film we have above referred to ensures, at any rate, a bleached lac which is free from chlorine, and does not partake, to any extent, of mechanical infirmity. The lac to be operated on is, in the first place, dissolved in strong spirits of wine, and to the solution is then added bone dust in sufficient quantity to make a thin paste, the bone dust, by the way, being finely ground. This mixture is allowed to stand for the space of several days, exposed during the time to the full action of direct sunlight; it is shaken up repeatedly during the period, so that every particle is brought into motion. When the shellac solution appears to be bleached sufficiently to suit the requirements of the operator, then the liquid portion is filtered off through an ordinary paper filter, and allowed to run into a bottle or other utensil.

If one filtration is not sufficient to obtain a clear liquid, then the solution is passed through a second time, but this is seldom necessary. Photographers who prepare their bleached lac in this way may be much more confident of its properties than they can of any commercial sample.

GELATINO-BROMIDE OF SILVER.

A CORRESPONDENT who signs himself "A Deaf and Dumb Artist"—a signature which excites sympathy for the difficulties under which he labours in experimental work—calls our attention to the fact that in 1866 he communicated with us regarding some experiments with gelatino-emulsions of iodide and bromide of silver, and, at a later date, with similar emulsions of chloride of silver. He now subscribes the following formulæ for the benefit of our readers:—

"GELATINO-BROMIDE OF SILVER PROCESS.—"Take—

- Bromide of potassium ... 3 or 4 grains
- Bromide of cadmium ... .. 6 "

Soak three or four grains of gelatine in one ounce of water and dissolve by heat, and mix the above salts with half of the gelatine solution. And then mix nitrate of silver twenty grains with the remaining half of gelatine solution. Drop a drop of the nitrate into the bromide solution at a time, and shake well every time a drop is added. The plate is then dried, washed, and coated with any preservative. When dry, fumed and developed. Gelatino-iron developer, or any developer will do.

- Iron ... .. 20
- Acid ... .. 15
- Alum ... .. quant. suf.
- Sugar ... .. 1 drachm
- Water ... .. 1 ounce

"GELATINO IODIDE OF SILVER.—"Prepare exactly as above, but use iodide instead of bromide.

"The washing is not used as in the bromide process, and no preservative is used.

"Developer for the above (any developer will do):—

- Pyro ... .. 3 grains
- Treacle ... .. ½ drachm
- Alum ... .. quant. suf.
- Water ... .. 1 ounce

Fix as usual.

### DR. MONCKHOVEN ON COLLODION LANDSCAPES.

IN a recent number of the Italian photographic journal, the *Rivista Fotografica*, appears an article upon the collodion best suited for landscape photography, from the pen of Dr. D. Van Monckhoven. The writer states that hitherto it has been believed that bromide of silver was more sensitive to the green rays, such as predominate in landscape, than the iodide compounds of that metal. This idea, as the experiments of M. Rutherford, when photographing the solar spectrum, sufficiently prove, is erroneous. The two salts are both equally sensitive, only iodide of silver solarises with much greater facility, and it is upon this circumstance that Dr. Van Monckhoven bases his new plan of operating.

By doubling, and even tripling, the period of exposure, it is possible to obtain every detail in masses of foliage reproduced by means of the camera, if one works with a collodion which has been sensitized with iodide salts alone. While the detail is being secured, those portions of the object which reflect a bright light are solarised in the picture, and thus they are no longer represented on the cliché as opaque blacks, such as is usually the case in landscape pictures. In this way a negative is secured with contrasts of a far less violent nature, and with the help of a suitable intensifying solution sufficient vigour may be obtained, subsequently capable of yielding upon paper a brilliant print, with a great deal of detail in the foliage.

M. Van Monckhoven recommends, therefore, all landscape photographers who are not required to produce pictures by instantaneous or rapid exposures, to employ nothing but simple iodised collodion, and, by allowing long periods of exposure, thus to secure less violent contrast, and more half tone and detail in masses of foliage and the like.

### Critical Notices.

**THE SHUTTLECOCK PAPERS.** A Book for an Idle Hour. By J. ASHBY STERRY. (London: TINSLEY BROTHERS.)

THE notice of a volume of charming essays amid the hard facts of photographic processes and formulæ will probably startle some of our readers as much as a sudden gleam of sunlight finding its way into the dingy recesses of the dark room; and the bare supposition that he could by possibility have an idle hour for which his favourite art could not find ample employment may be regarded by the perverid photographer as an affront. Besides luring him to spend some idle hours pleasantly, Mr. Ashby Sterry has another claim upon the photographer, as he assumes, in some sort, kindred with him in producing "sun pictures," and challenges Mr. Valentine Blanchard and others of the photographic fraternity to try conclusions with him. His pictures are produced without a camera, and he is unencumbered, in his sketching rambles, with dry plate or dark tent; groups, landscapes, or single figures are secured by an instantaneous process, and in permanent tints, by the aid of a crow-quill pen, or something as delicate in its touch. Quaint and picturesque, full of delicate humour and playful philosophy; characterized by a keen perception of beauty and fun, and hearty relish alike for each; these essays are in every way delightful. We were about to recommend them not simply for individual reading, but as a capital volume for the photographer's reception room, when we remembered that it might be inexpedient to give sitters an inducement for lingering there. In any case we commend to our readers a very charming volume.

**THE SILVER SUNBEAM:** By J. TOWLER, M.D. Eighth Edition. (London: TRUBNER and Co.)

PROFESSOR TOWLER'S very excellent and comprehensive manual has passed through many editions, and has been augmented extensively and curiously since it left his hands,

we imagine. The body of the work remains the same, but each edition contains an appendix giving fresh matter. The appendix, the addition of which constitutes the seventh edition, consists, for instance, of a number of articles transferred from one of our YEAR-BOOKS, and although their source is not acknowledged, they undoubtedly add to the value of the work. The appendix to the eighth edition is more extensive, and consists chiefly in the description of some useful apparatus and details of some recent formula.

**PHOTOGRAPHIC MOSAICS for 1874.** Edited by E. L. WILSON, Philadelphia. (London: PIPER and CARTER.)

MR. WILSON'S little annual is as full of capital practical papers as ever. Almost every distinguished photographer in the States seems to have made it a point of honour or ambition to contribute some details of experience to the general treasure, and the result is the very capital volume before us.

**THE MIRROR: A Weekly Magazine of Literature, the Drama, Science, and Art.** (London: JAMES HENDERSON.)

A NEW weekly magazine, in which science and art, as well as general literature, play a prominent part, might, under any circumstances, be very fitly brought under the attention of photographers; but the issue of a magazine possessing such unprecedented claims to attention as the *Illustrated Mirror* ought to be brought under the eyes of everybody who can read. It is, having regard to excellence, size, and price, probably the cheapest magazine ever issued. Its literary claims are of the highest class; its contributors men in the first rank; whilst in size and price it competes with the cheapest of its class. Amongst its contributors are George Augustus Sala, William Black, Charles Gibbon, William Sawyer, Tom Hood, E. L. Blanchard, J. O. Halliwell, J. Crawford Wilson, Tom Arher, Ashby Sterry, Dr. Carpenter, Dr. Chalmers, and a host of equally good men; and it is illustrated by John Proctor. Its contents present something for everybody, ranging from "grave to gay, from lively to severe," and admirably combining the qualities of a first-class literary journal with a magazine for general family reading. Photography receives frequent notice. Here is a paragraph we quote from the notes of passing events:—

One of the most popular recent applications of photography has been made in Paris. It consists in the issue of a first-class photograph with every number of a newspaper. The journal is entitled the *Paris Theatre*. The photograph is generally the portrait of an actor or actress. The photograph is of excellent quality printed by the Woodbury process, and consists in a portrait, the usual price of which would be about two shillings. The price of the journal in question, and photograph, is twenty centimes, or twopence.

**THE YEAR-BOOK OF PHOTOGRAPHY for 1874.**

Edited by G. WHARTON SIMPSON, M.A., F.S.A. (London: PIPER and CARTER.)

WE can only call attention to the fact that this YEAR-BOOK is issued; that it is larger than ever; and contains a larger number than ever of contributions from photographers, including almost every name of distinction connected with the art.

### PRACTICAL NOTES.

BY PROFESSOR HERMAN VOGEL.

**WASHING PRINTS—ALCOHOL IN SILVER BATHS—FOGGING BY ETHER—SPLITTING OF THE COLLODION FILM.**

*Washing Prints.*—The washing of freshly-printed albumenized pictures before toning is often termed "chlorizing." How on earth photographers came to adopt this name, goodness only knows. Many people believe, owing to

the term, that the pictures must in some way be treated with chlorine in the operation. This, of course, is a very silly blunder, over which some have worried themselves needlessly. I have repeatedly received letters from photographers in Silesia to the effect that their mountain water would under no circumstances "chlorize" their prints. They dipped their pictures into it, but the water remained perfectly clear, and therefore they believed the latter to be useless, and employed instead spring water containing chlorine, which had to be brought from an unheard-of distance. One correspondent told me that he had in vain bored for water which should be competent to "chlorize" his pictures; while another operator I know will not depend upon the water laid on in his house for washing his pictures, but has a supply of spring water carried up four pairs of stairs for the purpose. The most singular instance of the kind I know is that of a most fashionable photographer who endeavoured to add chlorine to his water supply by throwing into it a handful of common salt, the result being that his batch of prints became of a foxy red, and had to be thrown away.

To satisfy such brethren as these, I would point out what they should long ago have been acquainted with, viz., the washing of silver prints before toning is simply for the purpose of removing from them any free nitrate of silver still attaching to the surface of the paper. The water employed for this purpose need contain no chlorine at all, pure distilled water being quite as suitable, if not actually more so, than that which contains chlorine. If, during the operation of washing, the water becomes turbid or milky, chloride of silver being formed, this is due to the water containing by chance chloride of calcium or carbonate of lime, which is very frequently to be found in spring water. River water and mountain water contain less of these bodies, and are sometimes quite free from them; and in such cases the water remains quite clear after washing the prints; it is this circumstance, doubtless, that has misled many an operator, who, seeing no action, supposed that none had taken place. Many defend the employment of a water containing chlorine by stating that by means of the same the last trace of nitrate of silver is converted into chloride of silver; such is, however, by no means the case, for, according to Mr. Abney's experiments, a trace of free nitrate of silver is necessary in toning with the well-known chloride of lime baths. I am in the habit of dipping my prints four times into river water (which in Berlin contains very little chlorine), and then to tone them. Photographers who live in mountainous districts, and for years employ no water containing chlorine, will bear me out when I say that for washing purposes a chlorine water is in no way necessary.

*Alcohol in the Silver Bath.*—It is well known that with every collodion plate some alcohol and ether enters the dipping bath. The fact is that it compels us to make the developer more rich in alcohol, so that it may flow evenly over the sensitized plate. A thrifty photographer of my acquaintance, who is exceedingly economical in the matter of alcohol, is in the habit of pouring his silver bath, every afternoon, into a large saucer, and allowing to stand over night. The alcohol which has become added to the bath during the daytime is in this way evaporated, and there is no necessity then of adding any alcohol to the developer at all.

*Fogging by Ether.*—Fogging of the negative may be caused through many different causes, such as lack of acid in the dipping bath, stray light, alkaline collodion, organic substances, nitrite of silver, &c.; and recently I have observed that it may be due to ether. A supply of the latter had been obtained from an apothecary, and appeared to contain nothing of a suspicious character. The collodion prepared by it was found liable to fog, and the photographer attributed the defect to everything but the ether, and he endeavoured, by adding acid to the bath, iodising

salt to the collodion, &c., to get rid of the distressing phenomenon. The worst of it was, that in one bath in which the photographs were sensitized, others prepared with faultless collodion also showed signs of fogging. After every chemical employed in the process had been carefully tested, it was at last decided that the ether was at fault. On smelling the same, it was found to be mixed with some impurity, and upon another sample being employed for dissolving the pyroxiline, the defect disappeared. I may here add, that I have often remarked fogging with collodion prepared from precipitated pyroxiline when the normal collodion has not been completely separated, after it has been precipitated by the addition of water. In this case the defect cannot be removed, and the collodion must be thrown away.

*Splitting of the Collodion Film.*—The splitting of the collodion film has often given rise to discussion, and, till now, photographers have sought in vain for a means of preventing the same. In many studios such a thing is never to be heard of; as, for instance, in that of Messrs. Loescher and Petsch, of Berlin; while in others, again, costly negatives have been irredeemably spoiled despite the greatest care in storing the plates. In America, splitting of the film is quite unknown, and photographers over there maintain that the defect is due to the varnish, which is certainly, for the most part, better in America than Europe. The varnish is not, however, altogether at fault. Three years ago I brought back from America some excellent varnish, which I made use of; now I find in some of my films a tendency to split. M. Schuler's advice, which he gave some four years ago, is to coat the negative before varnishing with a solution of yellow (not white) dextrine, made up of one part dextrine and ten parts of water. If this were done, he maintained, no negative would split. M. Prumm, who has adopted this advice, has been most successful with his negatives, but the plan does not answer always, as a recent instance proves. One of the large printing establishments in Berlin changed its locality and moved with several thousand of negatives into new quarters. The walls were not quite dry, and, although all the negatives had been treated with dextrine, splitting of the film broke out like an epidemic throughout the series of plates. Dextrine alone, therefore, aids nothing; dry storage is also imperative, and that is the reason why splitting of the film is so rarely met with in America, where the atmosphere is much drier than it is in Europe.

## Correspondence.

### DISAFFECTION IN THE LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR,—I am obliged by the insertion of my letter in your last issue, and, with your kind permission, will add a few more words. I am anxious to do so (with no intentional discourtesy to the council) through your widely circulating journal, rather than (as you suggest I might) make my propositions direct to the Society. I do so, firstly, because that through your columns I reach every member of the Society; and, secondly, because I am anxious to do so at once, as I think that all suggestions having for their object any alteration of the Society's laws had much better be deliberately read and pondered by gentlemen in their own homes, rather than that they should hear them for the first time at the meeting called to (perhaps excitedly) discuss them.

I am sorry—very sorry—to see that this discussion is engendering personal, bitter feeling. Whether Mr. Stillman has cause for his complaint of discourtesy and coolness, one cannot gather from the Society's official report of the proceedings; but we all know that "actions speak louder than words." It is quite possible to offend in *manner*, while the sentences which drop from the lips are unexceptionable, and this gives point to a paragraph in your leader of the 16th inst., that "a society might be saddled with the permanent burden of an incompetent or disagreeable man." In my opinion, sir, such a possibility ought not to exist. The president, vice-presidents, with all other officers, ought to be periodically elected.

I am glad that, in your foot-note to my letter, you approve of giving the right of voting to country members. I will not dispute with you the non-conservatism of the council, and am glad to hear that it is at all times ready to receive suggestions from outsiders.

I must, however, join issue with you when you say that, "in proposing rotation as the sole rule of retirement, the Society would at times lose efficient and earnest officers, and retain many who, perhaps, never attend a single meeting of the council." But, sir, this supposed disadvantage is most completely met by Law 5, which says of those whose term of office has expired, that "all or any of whom shall, however, be eligible for re-election." By that "saving" clause *not one* efficient and earnest officer need be lost to the Society, for the bulk of the members want just such men to conduct their affairs, and, as I said before, are *sure* to re-elect them.

As to regularity of attendance, there ought to be a rule by which such attendance should be made known to the members, and that fact alone would have its influence on any laxity in this respect.

Let me repeat that I think the council (as such) ought not to initiate any election list, or take *any* steps which even *looks* like an attempt to consolidate their *own* power, or lengthen out their *own* tenure of office. In this, sir, they ought to "avoid the very appearance of evil."

Your last paragraph, where you say, "Facilities of the widest kind, and free from all taint of invidiousness, should exist for members electing new councillors," I endorse most emphatically, and, holding that opinion, I cannot see how you can consistently advocate the initiating of an election ticket by the council, for the very "event of any member proposing other names than those proposed by the council" *must*, in its very nature, be an *opposition* to the council, proclaims dissatisfaction with the council's ticket, would be looked upon as "invidious," fosters the spirit of party and eliquism, and must result in heartburnings and bitterness. If, on the other hand, there is but *one* list, and that list made only by the members, it must be free from all taint of invidiousness, and has nothing of an *official* character; it is simply and purely the "members'" ticket, and the members of the *council*, as members of the *Society*, could nominate any retiring members whom they wanted to re-elect, and could vote for them; but in their *official* capacity they should have nothing to do with it; if they do, they cannot escape the charge of partiality. Rule 7 is full of it.

It is a singular omission in the laws that no provision is made for the termination of the office of president or the secretary. I hope that, as well as other things, will receive the attention of the Society at the forthcoming general meeting.

Let me conclude by expressing a hope that at the coming meeting all personal feeling will be dismissed, that gentlemen will not be accused of "quibbling" on the one hand, or of "rudeness" on the other, that none—whether president, council, or requisitionists—will attempt to domineer, show partizanship, or a disposition to fight to the bitter end; but that *all* will go there with a determination to disregard any petty and unworthy annoyances to which they may haply be subjected, and, losing *themselves* in the far nobler aim of the good of the Society at large, and the highest interest of photography the world over, separate with the conviction that goodwill to each other (temporarily displaced) has a firmer grip and a closer hold than ever.—I am, dear sir, yours truly,

F. HUDSON.

Ventnor, Isle of Wight, January 26th.

#### GLYCERINE IN COLLODION.

DEAR SIR,—I often have to take large plates a distance from home, expose, and bring back to develop, and have always been more or less troubled with drying films. A few days ago, on one of these occasions, I added glycerine to the collodion, six drops to the ounce, and had no trouble. The plates kept perfectly, and worked throughout better than any I had ever used under similar circumstances.—Yours respectfully,

HENRY DIXON.

112, Albany Street, N. W.

#### THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

SIR,—On behalf of the committee of management, may I ask for space to acquaint photographers, both amateur and professional, that the Photographers' Benevolent Association is now established on a firm footing, the rules have been drawn up, approved by the Registrar, printed, and registered according to Act of Parliament, so that it has fairly commenced its legal existence. Some few of

the officers have been chosen, subject to the approval of the members at a general meeting to be now called for the purpose of electing officers to serve for this year. It is therefore necessary that all who wish to join and take part in the election should send in their names to the secretary, Mr. Wilkinson, 14, South Street, Bromley, Kent, as soon as possible. I may mention that the Rev. F. F. Statham, M.A., F.G.S., &c., has kindly consented to act as one of the vice-presidents, and Col. Stuart Wortley, and Captain Abney, R.E., have accepted the position of trustees, and that letters of kindly sympathy with the objects of the Association, with offers of a more solid support in the shape of donations and subscriptions, have been received from all the leading firms in London, and also from many well-known names among amateur photographers. It now remains for the assistants to take up the matter in the same spirit, and then we may hope to see the Photographers' Benevolent Association take rank among the foremost of similar associations in other professions. The amount of the subscription has been purposely made low, to allow all classes of assistants to take advantage of its help in case of need. The committee also invite amateurs, as they love the art they practise for amusement, to assist in helping those who have to practise it for daily bread, by donation or subscription. Mr. Wilkinson will be most happy to answer any enquiries, and donations and subscriptions will be received by the London and County Bank, Bromley Branch.

The necessity for such an organization has been acknowledged. The few earnest men (mostly assistants) who have by the expenditure of time and money brought the crude scheme to such a successful issue, now invite the cordial co-operation of all photographers to place this association in the position it ought to occupy as the Benevolent Association of a profession of such importance as photography.—I am, dear sir, yours truly,

GEORGE CROUGHTON, Chairman of Committee.

10, Ashchurch Grove, Shepherd's Bush, W.

#### PHOTOGRAPHIC SOCIETY FOR DUBLIN.

SIR,—Would you permit me, as a reader of your invaluable and influential journal, to suggest the promotion of a photographic society in our city. The want is so intensely felt by both old and young in the art that our winter months will be tedious beyond description. In Dublin, where there are so many men of such high repute, and well classified students in photographic art, the benefits derived by interchange of ideas, and the source of information to be acquired by old and young, at these convivial meetings, it is needless to enter into detailed comments upon. I feel convinced that those dark room manipulators we so highly eulogise, such as Messrs. Millard and Robinson, Simonton, Lauder, Lawrence, and a host of others (too numerous to occupy your space with) would all assist in the promotion of such an institution. I trust that you, Mr. Editor, will aid me in giving publicity to this. Our city, compared with others, produces an equal number of masters in the progressing art of photography. They fully credit that its progress may be attributed to such societies—that such societies brought it from its infancy to its teens. "And still we are not happy." I trust that my English brethren will acquit me from advocating a subject so strongly on the *tapis* (I mean home rule) by endeavouring to obtain a furtherance of internal management in photographic affairs, being assured that such a society would meet with satisfactory support from professional and amateur.—I remain, sir, trusting that this may be suggestive of starting one, and apologising for trespassing on your space, so freely given for the promotion of photographic intelligence and art studies, respectfully yours,

JAS. BRISCOE GILBERT.

26, Capel Street, Dublin, Dec. 18, 1873.

[We give insertion to the suggestion of our correspondent with pleasure, and shall be glad to learn that some steps have been taken to give them effect. We shall have pleasure in aiding in any way which we can.—Ed.]

#### BLISTERS IN ALBUMENIZED PAPER.—ALBUMENIZED GLASS.

DEAR SIR,—On turning over the past year's numbers of your paper, I find several notices of blistering of albumenized paper. Many causes and remedies are suggested, but I do not find that any one has thought of the variation in temperature, between the different baths and the waters for washing before and after fixing, as a possible cause; I fancy the hyposulphite of soda fixing bath is usually much colder than either the toning bath or the washing waters.

A useful brush for albumenizing glass plates, or for any purposes

to which a Buckle's brush may be applied, can be made out of a strip of glass, one inch to four inches or more wide, and a piece of sponge (fine), cut partly through, into which a portion of the glass strip is inserted, and secured by an elastic band; there are no fibres to come out, and the brush is easily kept clean. J. C. S.

[Our correspondent forwards us an example of the ingenious little brush he suggests. It is excellent.—Ed.]

#### DIRECT PICTURES *VERSUS* ENLARGEMENTS.

DEAR SIR,—I should like, with your permission, to add to the observations I made at the South London Society, on the size of the large direct heads at the Crawshay Competition. That eight inches is much about the average of the human face, taken from the bottom of the chin to the parting of the hair, is beyond question. I measured several male faces, but none of them came quite up to that standard, while others were much below it. Much was lately said in praise of two life-sized heads by Mr. Neilson; and you, sir, expressed a regret that they had not been sent to compete. It would, however, have been useless, as the faces were only seven inches in length. With regard to the ladies, I found they were simply out of the question, if I would adhere to the actual size of nature. I measured three or four, and found the length of the face varied from six inches to seven and a quarter inches. This decided me, and although I had purposed competing for the larger size heads, after a few trials I determined to go in for the five inches focus only.

It is not at all likely that I shall have the time, even if I had the inclination, to compete again for either of the prizes. I do not, therefore, write from any motive of self-interest, but rather to clear the path of my photographic brethren at the next exhibition; and also from a belief that much more may be accomplished in the way of large direct pictures than has yet been done. I cannot suppose that Mr. Crawshay really prefers quantity to quality: still less do I believe that he would willingly do anything to bring discredit upon that style of portrait photography with which his own name is so worthily associated; yet what, I ask, has been the result of the competition? The enlargers have certainly carried off all the credit of display. The larger-than-life-size heads (as I must persist in calling them) have been spoken of in very disrespectful terms: the features were commonly said to be distorted—the noses, especially, too large and too broad—and even the word *monstrosities* was freely applied to the pictures. At the last meeting of the South London Society, also, upon the question of “direct pictures *versus* enlargements,” the direct pictures were, as you truly observe, simply “left out in the cold.” To me this does not appear to be altogether just.

I need scarcely say that I have no prejudice against the enlarging processes. Some of the heads of Mr. Edwards at the Exhibition were very fine (although I still think much of the effect due to retouching) and the two large portrait subjects of the Autotype Company were really splendid. I believe, however, that up to a certain point the large direct pictures have a quality not to be found in any enlargement. Take, for example, the smaller heads of Mr. Crawshay, or the pictures of Slingsby, Blanchard, or Robinson: I have yet seen nothing at all resembling them produced by any method of enlarging. I believe that the future progress of photography depends far more upon the right and ready use of the larger lenses than upon any number of carte negatives, however easy it may be to take or to enlarge them.

“Mais revenons nous a vos moutons.” I quite admit that it is possible (although troublesome) to find male heads of the required size; but how about the ladies? To furnish an exhibition of this sort with the fairer half of it left out would simply be to re-introduce the old joke of the play of Hamlet with the character of Hamlet left out by special desire. If we are to introduce only those who have faces eight inches long, I fear we shall have to go to Patagonia for models. As I have said, according to the standard proportion, as derived from the finest Greek sculpture, and universally acknowledged by the moderns, a face of eight inches supposes a figure of six feet eight inches. I will not quote Burke, who, in his essay, lays it down as an axiom that the beautiful is always inclined to littleness; nor further refer to Sir Joshua Reynolds, who seems, in some of his loveliest heads, to have acted upon that idea of his friend. I will simply mention, as an illustration of my argument, the Venus de Medici, the finest complete female figure left us by the Greeks: this is about five feet two and a-half inches in height, and consequently has a face but little over six inches in length.

I will here mention the plan I adopt for ascertaining the precise length or proportions of the features—a plan I have found

of great use in painting life-size portraits. Place a strip of card-board perpendicularly against the face; with a pencil mark the distance from the bottom of the chin to the parting of the hair, and, if necessary, the places of the features; hold this against the ground-glass of the camera, and it will then be impossible to depart from the true size of nature without knowing it.

Under all the circumstances, I think we may fairly appeal to Mr. Crawshay to reduce the size for male heads to seven inches, for female to six and a-half inches: or, better still, to reduce the standard generally to the latter size, and leave any competitor who may find it desirable to make the heads as much larger as may be convenient to him. I believe the result would be that the heads in next year's Exhibition would be of a finer quality, and also of a much more pleasing character, than the last.—Yours respectfully,

R. W. ALDRIDGE.

### Proceedings of Societies.

#### MANCHESTER PHOTOGRAPHIC SOCIETY.

The monthly meeting was held at the Memorial Hall on Thursday evening, the 8th instant, Mr. W. T. MABLEY, President, in the chair.

The routine business being disposed of, Mr. G. H. Wharton was elected a member of the Society.

Mr. A. BROTHERS, F.R.A.S., then communicated some particulars on the fading of silver prints (see page 49). He commenced by reading some extracts from articles which had recently appeared on the fugitive character of photographs, and expressed his belief that such articles were very damaging in their tendency. He then exhibited a number of silver prints, most of them taken from the “Pencil of Nature.” The first shown was more like a sheet of dirty yellow paper than a photograph, and some of those shown subsequently were very little better. In every instance the fading had taken place in that portion of the print which had been pasted or otherwise attached to the mount. One print shown by Mr. Brothers had been produced by himself for a special purpose some fifteen years since, and although it had been hastily done, and had not even been washed after the hypo bath, it retained its original colour and freshness.

A short discussion followed, in which

Mr. PETTY testified to the inferiority of modern white paper for retaining its colour. He said good white papers in times past were made from picked white rags, while in the present day bleaching processes were much resorted to on materials less carefully selected.

Mr. JOHN HOLDING said it was difficult, almost to impossibility, to procure either drawing-papers or colours that were sufficiently permanent.

Mr. ATHERTON said years of experience had satisfied him that freshly-made starch was the best medium for mounting purposes.

The SECRETARY said the objections urged against ordinary paper and mounting boards ought not to apply to photographic paper if all the care ascribed to its manufacture had been exercised.

The PRESIDENT agreed with Mr. Brothers to some extent, but did not consider silver prints by any means permanent, in consequence of the great affinity silver was known to have for sulphur.

A MEMBER suggested that the gold toning of silver prints would tend to their stability.

The PRESIDENT said no doubt it would, to some unknown extent.

Mr. NOTON read an Appendix to his paper on Limes (see page 51). He exhibited a much better light than that obtained at the December meeting. This was in some measure due to the greater pressure of gas in the mains.

The pressure of coal gas at half-past five o'clock was twelve-tenths of an inch of a vertical column of water; at six p.m. it had increased to more than thirteen-tenths. Some oxygen was obtained from Mr. Noton's apparatus, and a trial made. The light was very poor, and the gases exploded and put out the light several times—the large bore jet being used. At seven o'clock the pressure had increased to twenty-tenths or two inches, and all went well, a good light being produced, showing the pictures well on the screen. The blowpipe was afterwards taken out of the lantern to show the naked light, and the great facility there was for removing, replacing, or substituting another lime, even without extinguishing the flame of the blowpipe. A cylinder composed of magnesia alone was tried; the light, however, was not equal to that of the lime and magnesia.

The meeting, which was a full one, passed a vote of thanks to Messrs. Brothers and Noton, and was then adjourned.

## Talk in the Studio.

**PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.**—We have received a copy of the Rules of this Association, which have been duly registered in accordance with the Friendly Societies' Act. It is matter of congratulation to those who have long and earnestly worked in connection with this idea, to find it assume the form of an established fact. We hope shortly to notice the rules further.

**PHOTOGRAPHY AND THE TICHOENE CASE.**—It will be satisfactory to photographers to note that the discredit of what has been termed the "garbled photographs of the grotto" is not laid by the prosecuting council to the charge of the photographer. Mr. Hawkins, in a fierce onslaught upon Mr. Onslow, remarked, in his concluding speech:—"We see now why he did not deem it inconsistent with, and derogatory to, the character of an English gentleman to procure false and garbled photographs of the grotto. I do not make any charge against the photographer, but I accuse Mr. Onslow of getting the views taken from a point that would not give you a fair representation of the grotto, and I accuse him of doing that with the deliberate intention of misleading you. And I say shame upon him for it. Henceforth let his name always be associated with the grotto. Let him have those two photographs: he has bought them and paid for them. Let him keep them, and hang them on the walls of his ancestral home, and let them go down to generation after generation as heirlooms of the family of Mr. Guilford Onslow."

**BEAR-HUNTING AND PHOTOGRAPHY.**—In an account of bear-hunting within the Arctic Circle, the *Lamp*, after describing the manner in which the retreat of a bear with her two cubs was cut off by the steamer, continues:—"At this moment the photographers, rushing on deck, demanded the right of 'first shot.' Quick as a flash the camera was down and focussed, and the family group of bears was taken at a distance of about two hundred yards. The camera was stationed upon the top-gallant-forecastle, and the impression was obtained while both bears and ship were in motion!"

## To Correspondents.

**GUM.**—The practice of applying a solution of gum to a negative whilst wet to secure a surface for retouching, and subsequently varnishing, was much practised a few years ago, but was given up by the majority of portraitists on account of various disadvantages which were found to arise in practice. Gum, being very absorbent of moisture, was found to absorb damp in spite of the varnish, and frequently to cause cracking. Dextrine was found to be a good substitute for gum, and to involve much less risk. The use of a thick solution of gum—such as you describe—is necessarily dangerous. Any solution of the kind should be used as dilute as possible; but the application of such substances to a negative, in order to obtain a retouching surface, has been superseded by better methods, involving less trouble and risk. The use of a retouching varnish, or the mode of making portions of an ordinary varnished surface suitable for retouching, either by application of a little turpentine or rubbing with powdered resin, or by other methods we have described, and touching upon the varnished negative, is now almost universally adopted, and is found to be less trouble, as well as safer.

**C. W. V. A.**—Plain paper may be waxed by immersion in melted white wax. A flat dish is used, and the wax being melted in it the sheets of paper are immersed, and subsequently placed between sheets of blotting-paper and submitted to the pressure of a hot iron. Many samples of paper are better for being previously soaked in warm water, to remove a portion of the sizing matter.

**CONSTANT READER.**—Nothing is better than the acetate bath for giving warm, rich tones. Take one grain of chloride of gold, thirty grains of acetate of soda, and six ounces of water. Use a day or two after mixing. Fix with four ounces of hypo in a pint of water.

**FRANK.**—Your description of fine lines running to the corner of the plate in which the collodion was poured off is a little indefinite. Are the lines of an irregular crapey character? If so, it is the fault of the collodion, which contains too much water—that is, the ether and alcohol employed is insufficiently rectified. The defect is known as "crapeciness" in the collodion, and there is no remedy. You may, however, to some extent, modify the defect by allowing the collodion to set well before immersion in the bath.

**A LEARNER.**—The portrait lens in question may be used for landscapes, using a small stop. A view lens, as commonly understood, is a single lens of the form of that which constitutes the front lens of a portrait combination. If you unscrew the front lens of the portrait combination, and screw it in the place of the back lens, turning that which was the back to the front, you will have an ordinary view lens. 2. The above background will answer well for a small room, and will permit you to dispense with blinds.

**ARTIST.**—We have worked on carbon prints with crayon after first applying a coating of "Newman's Preparation," which gives a dull surface, presenting a tooth to the crayon, without in any way interfering with the beauty of the print.

**J. C. S.**—So far as we know, nothing further was done, a sufficient number of subscribers not having come forward. At present the gentleman referred to is out of England. We do not think that either absolute certainty or good keeping qualities will be obtained with any process similar to the albuminate of silver process, in which a combination of an organic substance like albumen and nitrate of silver are present. One of the most certain processes is the ordinary collodio-albumen, and its keeping properties are placed beyond doubt when a final wash of gallic acid is applied. Probably M. Constant's new process will be found to combine all that is required. Liquid ammonia may be used in alkaline development, but Col. Wortley recommends carbonate of ammonia in the proportions we have before published. Liquid ammonia may be used, but it is an experimental matter, rendered more possible by Colonel Wortley's recent discovery.

**R. F. M.**—The photo-relief process is now free from patent restriction, the patent having expired; but it possesses the still higher protection of requiring the original patentee's skill and experience to its successful working. We have no doubt that, for a suitable consideration, he would impart all necessary information; but you must bear in mind that the experience of many years in working out a special process is an important capital, the equivalent of money.

**SUNDAY TRADING.**—A "Poor Photographer" writes to protest against the imputation he thinks contained in Mr. Tunny's allusion to Sunday labour amongst photographers, and asks if it apply to Scotland only. In this country he thinks that Sunday labour is chiefly confined to the class who work at a low rate, and whom he ranks with dealers in sweet-stuff and penny cigars. On the whole, he believes that all respectable photographers regard the day of rest with due respect. We summarise our correspondent's letter, but we cannot open our columns to a discussion of the question of Sunday labour.

**ANTOINETTE AND JUNANITA.**—Photography in Malta will doubtless be characterized to a considerable extent by similar conditions to those which prevail in warm climates generally. 2. We cannot say certainly that any commercial dry plates will keep four months between exposure and development; we doubt it. 3. Portraits can be taken on Liverpool plates in a good light. We have taken portraits thereon. 4. No substance of any kind should come in contact with the surface of a sensitive dry plate, either before or after exposure. India-rubber bands (not vulcanized), one at each end, are the best aids in packing. 5. The defect you describe commonly arises from the sensitive carbon tissue having been kept too long in a damp place, and so become slightly insoluble. Sometimes it happens from not leaving what is described in the Autotype Manual as a safe edge. 6. Carbon prints can be transferred to wood without difficulty. A slight preparation of the surface with gelatine would be desirable. Get the new edition of the Autotype Manual.

**W. J. STILLMAN.**—We have received, just before going to press, another letter from Mr. Stillman, too late for insertion. He reiterates his conviction that he was not placed on the retiring list because of infrequent attendance. It is scarcely worth while to repeat our assertion that he was. He now states that he has never affirmed that the letter to which he attributes his trouble was discussed in a council meeting, but merely that it was attacked by members of council. But if he did not intend to imply that it was in their capacity of councilmen, he might as well have said that it had been attacked by members of the Society or by members of English society at large. On other points he affirms his correctness, unless statements made to him by "gentlemen of recognized probity" be inaccurate; that is, his statements are based upon hearsay, and therefore possess all the vague uncertainty of statements repeated over by two or three persons, no matter how high their probity. As an illustration of the value of hearsay, Mr. Stillman proceeds to inform us that Mr. Swan was dejected to become, as he (Mr. Stillman) was informed, of his non-attendance when a member of council. Mr. Swan never was a member of council, and yet we have no doubt that Mr. Stillman was informed by gentlemen of "acknowledged probity" that he was. They were mistaken, as Mr. Stillman is in most of his statements on the questions in discussion.

Several Correspondents in our next.

## The Photographic News, February 6, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PHOTO.-SPECTROSCOPES — PRINTING BY CONTINUATION — MICRO-PHOTOGRAPHIC DIAGRAMS.

*Photo.-Spectroscopes.*—About three years ago Mr. Rutherford, of New York, whose wonderful photographs of the moon must still be fresh in the memory of every photographer, made an interesting discovery in regard to the spectrum of the sun. As most of our readers know, when a sunbeam is refracted by a prism, there are seen not only a series of colours ranging from red to violet, but certain lines which indicate the presence of different elements and compounds in a state of combustion at the source whence the light comes. Indeed spectrum analysis—or, in other words, the examination of a body in a state of combustion by means of a spectroscope—has now become regular branch of chemistry and physics, and affords a ready means of ascertaining the constitution of different bodies, the bright lines shown, according to their position in the spectrum, their nature, &c., indicating the presence of certain elements or compounds. Rutherford found that looking at the spectrum optically, or recording it by means of photography, furnished two different results, for some lines which were seen by the naked eye were not recorded by the camera, and others again were shown upon the sensitive plate of which the human observer was totally ignorant. Thus in the violet and ultra-violet end of the spectrum the sensitive plate proved lines to exist of which no sign appeared upon the accredited tables of Kirchhoff and Angstrom, while there were some, again, faintly indicated by these philosophers, which the camera in its turn reproduced most vigorously. One thing was very evident, therefore—that no spectrum analysis could be declared to be perfect without the aid of the photographer, for until both optical and photographic observations were made and compared, the research could not be deemed complete. Very recently Dr. Draper has confirmed Mr. Rutherford's observations, and a very excellent photograph of the spectrum was recently issued in *Nature*, which that gentlemen had produced. Mr. Norman Lockyer, F.R.S., whose name as an astronomer stands very high, employs the camera with great advantage in his spectrum work, and has, indeed, found the instrument indispensable in carrying out some of his observations. He has, too, made several discoveries of importance, which, as they owe their origin entirely to photography, deserve our especial attention. The lines of which we spoke just now differ in length, and the longest line is the last one to disappear; or in other words, a body which contains but a small percentage or trace of an element will show a long line corresponding to that element, and nothing more. If a larger proportion of the element were present in the body under examination, then the lines would be repeated, but of shorter length. This fact Mr. Lockyer seems to have proved in a most decisive manner. He allows only a very small amount of sunlight to enter his spectroscope, through the tiniest slit imaginable, and photographs the result; he then opens the slit wider and wider still, obtaining a photograph at every movement, and he finds then that the long lines are the first to appear, and the last to disappear. One other very important fact seems evident, so far as his experiments go, viz., that most of the elements have their lines in the violet portion of the spectrum; in that part, therefore, where the sensitive film has been found a much more critical observer than the human eye; and this is one more reason for supposing that a photo.-stereoscope will in future be a necessary piece of apparatus to every chemist and physicist. Mr. Lockyer's observations seem to point out that only those bodies which have their lines in the violet are really elements, and for this reason it is inferred that bromine, iodine, and chlorine, which do not show in

this most refrangible part of the spectrum, may not be elements after all.

*Printing by Continuation.*—It is a little ridiculous to find things done in a wholesale manner, while the possibility of their being accomplished at all is still an unsettled question in some minds. In Paris there are still those who uphold that the theory of continued actinic action upon a bichromate film is a false one, and not borne out by evidence, notwithstanding the evidence which Mr. Johnson, Captain Abney, and Mr. Priteliard have adduced upon the subject. Two years ago we reported that at Woolwich, at the General Photographic Establishment of the War Department, carbon prints were produced by hundreds in unfavourable weather by the method of merely half printing in the pressure frames, and then allowing the action to go on afterwards for hours in the dark, a considerable time being permitted to elapse between the exposure of the sensitive tissue to light, and its development in warm water. At the time we refer to prints were produced at Woolwich in every respect equal to pigment pictures which are printed wholly in the light, and in this way the work was carried on in full swing through the winter. During the last few months the same plan has again been resorted to, of printing rapidly, the production of photographs connected with the Gold Coast Expedition necessitating pushing forward of the work. The tissue is exposed to light under a negative about three-fifths the time required to give a fully-printed result, and the incipient picture is then put away in a box to be developed the next day. It was found that in bad, wintry weather, such as we have lately been having, only as many as six degrees were marked on the actinometer throughout the day—that is to say, the sensitive paper only coloured deeply six times from morning till night—and this was, as a rule, barely sufficient to print two pigment pictures, the average negative requiring about three tints, or rather more. Therefore, by only half-printing, or little more, the gain in time is very great, and half the number more pictures are got off than in the ordinary way of printing. This plan, we are told, has been carried on at Woolwich for the past two months, and with great success. Some care is, of course, necessary to time exposures correctly, and not to overlook development when the proper period has elapsed; but no more failures are obtained by this method of printing than in the usual one. Another fact connected with carbon printing is worthy of record. When the Woolwich establishment first adopted carbon printing, several years ago, the usual run of negatives were much too dense for the work, and sometimes as many as twenty, and even five-and-twenty, tints had to be recorded on the photometer before a negative was sufficiently printed. Since then it has always been an endeavour to get thin negatives, which give more vigorous prints in carbon than they do in silver, and now clichés are seldom taken at the establishment which require more than three or four tints, copies being fully printed from them in the summer in five or ten minutes.

*Micro-Photographic Diagrams.*—Colleges and schools are rapidly finding out the great value of micro-photographs as a means of imparting instruction. In medical schools, especially, the aid of photography in this way is beginning to be found most essential, for large diagrams, produced by the aid of the camera and microscope, of various medical preparations, are found very useful. Not only does the employment of microscopes in classes often prove inconvenient, but the cost of such instruments, if they are good, is a great obstacle to their employment, and for this reason carefully executed enlargements are much sought after. Another thing is that it is difficult for the professor to point out such and such a portion of an object while a student is examining it in a microscope, while no such difficulty can arise if a bold diagram of the subject is before the students.

## THE CHEMICAL ACTION OF LIGHT.

BY W. T. BOVEY.

ALTHOUGH that phenomenon known as actinism is so intimately related to solar physics, and its existence was familiar to scientific investigators long prior to its enlistment in the service of photography, until recently no theory propounded has afforded the slightest clue whereby a satisfactory elucidation of what would appear to be an insoluble problem could be extracted. Hardly would it have been possible, however, for so important a matter to have long remained unnoticed by photographic practitioners, whose art owes its very existence to the agency of actinism—an agent so potent, invisible, secretive, almost unfathomable, mysterious. And to photographic investigators science will one day doubtless be indebted for a new and fascinating chapter added to men's knowledge of hidden nature.

A correspondent, W. J. C. M., intelligently enquires recently in the *News*, "What if these hitherto called chemical rays should prove to be the electric part of light?" In reply, I would observe that the views suggested in the query quoted harmonize to completeness with an opinion published by myself years ago—an opinion which derives something akin to conclusive support from the investigations of that eminent natural philosopher, Mr. Crookes, who, on the 11th of December last, described before the members of the Royal Society an important discovery in natural science which goes far to identify actinism with electricity. The particulars of the experiment are described in the *Daily Telegraph* of Dec. 13, in the following words:—"He (Mr. W. Crookes, F.R.S.) suspended an exceedingly light lever arm of glass, about one and a-half inch long, to the end of a fibre of spun glass about eight inches long, inside a glass tube. To each end of the lever arm a disc of pith, rather smaller than a threepenny piece, was fixed. As soon as the tube was filled with air, the warmth of a finger outside the tube almost instantly repelled the lever arm. When there was a vacuum of thirty millimetres, which is easily produced with a common air pump, external heat would not move the lever arm. On the very perfect vacuum produced by a Sprengel pump being tried, the lever arm was repelled by the warmth of the finger. Light also attracts or deflects the lever arm under like conditions."

It is to be hoped that some experimentalist, with means and leisure, may venture on a step omitted by Mr. Crookes, for if it can be shown that, with the use of orange-coloured glass, the light loses its power to attract or deflect the lever, the relationship of actinism with electricity will no longer remain a matter of speculation or doubt. The question which matter-of-fact querists would perhaps be inclined to raise in connection with this matter would be to ask, What possible advantage could arise from even a perfect acquaintance with the nature and sources of actinism? No one may venture to predict. One feature of the case, however, is one of certainty. Newton's theory, based on an investigation of the constituents of light, afterwards amended by Dr. Brewster, would, perforce, undergo another, perhaps a final revision, as we have only to move one step beyond an investigation of the electric influence of light to commence an inquiry respecting the source from whence the electric division of solar light emanates. As far as present knowledge extends, we are required to pin our faith to a theory which supposes a ray of light to consist of three parts, representing three distinct physical qualities—viz., heat, light, chemical actinism, the yellow ray being accredited to light, the red to heat, and violet to actinism. Now, it has always appeared to my understanding, from the moment my mind became interested in this inquiry, that the idea of combined properties attached—or rather, I might say, that are said to be centred—in solar light, is far too complex in detail to be indisputable. Personal and persistent observation of many phases of natural phenomena has convinced me that,

in scientific exploration, the further we diverge from simplicity the greater grows the distance from truth. Before we adopt, as finally, the Newtonian theory of compound solar rays, we should do well to see a reason why that the actinism of spring time decreases its force as solar heat graduates from temperate to the swelter of summer intensity as summer months roll onward. Surely there is inconsistency embodied with a thought that favourably admits actinism to be an emanation from the sun direct, one of those threefold threads said to be spun into a single solar ray, because such thought makes the sun itself to act inconsistently, inasmuch as the constituents of its rays must vary at different seasons of the year: weak in actinic force in winter; not so weak, but still comparatively feeble, when the sun has reached its summer altitude; strongest in spring time, and but a trifle less of strength in late autumn. And it is worthy of note that, at such times as actinism is found inactive, free electricity is most prevalent, thus indicating that the condition of actinic electricity is latent, to ordinary tests insensible. What electricity really is, we have yet to learn. There can, however, be no doubt that it is the most important, if not the vital, force of nature; and it is more than probable that in the action of that force is centred the mystery of life, the economy of the growth of vegetation. And, in reference to this last, it is a fact which I have often tested, by direct experiment, that the cause which induces the leaves of plants to turn towards the light may be attributed to electric influence. If this is doubted, a very simple experiment will serve to prove the sensitiveness of plants to such attraction. Excite a glass rod by means of friction against some wool fabric—such as dry flannel—place the excited rod near a freshly plucked leaf or blade of grass, when it will be observed to bend toward the rod; sometimes to cling to it for two or three seconds.

The question naturally arises, when we consider the improbability of a change occurring in the constituent proportion of light-rays at any period of the year, how may we account for the existence of actinism if we separate it from immediate solar emanation? Let us, with Descartes, suppose light to be the result of undulating or wave-like movements, the oscillating motion occurring with inconceivable rapidity. Let us endeavour to conceive those undulations of solar rays moving in the vicinity of a girdle of subtle electric fluid that in a latent and changeable state is mingled with our atmosphere, and it becomes apparent that the disturbance wrought by the oscillations would bring about a corresponding movement in the electric medium, inducing a state of excitement that would probably be repellent towards the disturbing cause. The result of such antagonism would be heat, on the one side, with electricity set free on the other, plus a power developed known as actinism. This statement may appear to be the offspring of rambling thought, an illusion wrought in the mind of a visionary; but if we glance for a moment at an analysis of the solar spectrum, and observe the extreme refrangibility of the actinic violet ray, we notice that our theory fits in with known facts. Why the greater length of violet rays? Why the chemical power that exists beyond the visible line of violet light? If we can imagine this violet ray independent of and in antagonism with the real solar light, we have at hand a reasonable explanation; as the separation induced by the prism would give room for the excited rays to diverge to the fullest limits, and the vibrations, becoming weaker as they reached the outer visible edge, would extend beyond that limit, their activity being insufficient to create light, yet still enough to maintain chemical action.

To produce every argument that could be adduced in support of the theory here laid open to criticism would exhaust the limits of a volume. Suffice it, however, at this time to produce a sufficiency of reasoning to show that the letter bearing the initials "W. J. C. M." is based on sound judgment.

## BE SURE YOU'RE RIGHT—THEN GO A-HEAD.

BY W. HEIGHWAY.

ONE of the principal, and, perhaps, most difficult things to the young practitioner, who finds himself set adrift on the troublous sea of photography, is in the selection of a reliable set of formulae. To get advice of a good practical photographer is not always possible, and the only thing for him to do is to beat about, irresolute and uncertain, between the numberless good rules of working set down in our journals and books, until he worries out for himself some mode of working; unless, weary and dispirited, he perishes miserably in the attempt, and is wrecked on the rock of good advice.

In the case of the amateur, this catastrophe does not come home as a lesson to be learned and profited by, but all, more or less, suffer by an uncertainty, engendered, in a great measure, by carelessness in working out a "good idea," suggested by some generous discoverer.

To properly test a suggested improvement, we must follow out the directions patiently from beginning to end; understand perfectly the nature of each ingredient, and the collective results; then, and not till then, is it wise or right to modify the formula, and begin to experiment on one's own account. Many suggestions are cast aside as useless, only because, in testing them, part only of the ground has been gone over; and an incomplete formula is simply *no formula at all*.

The best advice to be given to operators about to experiment in this lame fashion is, *don't*.

Even in the daily routine of gallery work, there is too little thought and discrimination brought to bear on the work. We go too far, or not far enough, and leave too much to good luck, and, believe me, this happy-go-lucky argument has no weight with photographic chemists.

For an instance, the nitrate of silver bath. Take one which is charged with alcohol and ether, and, save in this respect, is perfect. We ought to know with certainty in what condition it is, each cause of failure producing certain effects, and these we should be educated to recognise. But to our alcoholic bath. How many there are who would set to work to doctor it for general debility. First, it is reduced by an addition of water, and filtered. This removes a great deal of iodide, which is necessary to its health. The bath is then neutralised with carbonate of soda or ammonia, and then boiled, and again filtered. When all it needed, in the first place, was an hour's "boiling down," which causes an evaporation of the alcohol and ether.

In the same random manner are other portions of our work performed, and I might cite many instances if it were necessary; but it is far from my wish to adopt the tone of the censor. Let us all think well what we are about, for ours is a profession requiring a great deal of nicety and discrimination. Think before you act. Think of what you have to do, and why you do it, and there is then little fear of going wrong.

## KRONÉ'S DRY PLATE PROCESS.\*

AFTER the plate, coated with silver collodion, has been brought into the iodide of potassium bath *c*, it is allowed to remain there quietly for half a minute (in the bromo-iodide of potassium bath *e* 1 the plate must remain for at least ten minutes, because the formation of bromide of silver takes a long time to form; in this case, the plate is allowed to remain in the bath while a second one is being prepared). It is then agitated, in order to dissolve the alcohol and ether in the film in the watery fluid. After the lapse of a minute, the greasy markings on the plate disappear, and the film is then lifted from the bath and rinsed with ordinary water. As iodide of potassium (as also bromide of potassium) is easily dissolved in water, this rinsing of the plate is very soon accomplished, but

little water being required, and the plates are rendered thereby perfectly clean. After use the bath is filtered back into the stock bottle, and, when the quantity diminishes, fresh solution is added.

The iodide of silver now upon the plate, from the fact of its being formed in an excess of iodide of potassium, is insensitive to light, for only when the salt is produced in an excess of nitrate of silver is it acted upon by luminous rays. In this insensitive state the plates may be dried, and kept for subsequent employment. On the other hand, plates prepared in the bromo-iodide bath contain iodide of silver that is sensitive to light, as also sensitive bromide of silver, and for this reason must be sheltered from the action of light.

To render the plates ready for employment in the camera, we prefer before all sensitizers, so far as our experience goes, nitrate of silver, because this forms with resinous matter an organic compound, something analogous to albuminate of silver in the collodio-albumen process. A silver bath prepared according to the under-mentioned formula is what we make use of:—

*f.*—Silver Bath.

Nitrate of silver...	...	6 grammes
Distilled water ...	...	100 cubic cents.
Iodide of potas. bath <i>e</i>		3 drops

In the case of bromo-iodised plates, three drops of the bromo-iodide of potassium bath *e* 1 are substituted for the last named.

The silver is dissolved in the water, and the iodide of potassium bath dropped into the solution, which is afterwards briskly shaken. The greater part of the freshly-formed iodide of silver is dissolved in the nitrate of silver, and for this purpose the mixture is allowed to stand overnight, and filtered next morning. The silver bath does not require to be strengthened, for the slight consumption which combines with the resin may be disregarded; therefore, when the stock gets low, a fresh quantity is added, care being taken to filter the liquid every time it is poured back into the stock bottle after use.

The iodised and washed plates (either just washed, and, therefore, quite wet, or taken from store, where they have been in a dry state for some time) are now brought into the silver solution, contained either in a vertical or flat bath. The plate remains for half a minute in the silver bath, the solution not requiring agitation during the period, at any rate if a vertical dipping bath is employed. After the plates have been taken out and drained, they are passed into a flat bath of clean water, in order to weaken the envelope of silver surrounding the plate, by gentle motion therein; then the film is further washed, by means of a fine rose from a watering pot, and dipped under water two or three times with the hands, and finally it is rinsed with filtered water. Some attention must be paid to this washing of the plates after sensitizing; the operation cannot be dispensed with, and upon its being efficiently performed depend the keeping qualities of the plates. The latter are placed to dry in a drying cupboard, or in an open box, covered with thin stuff, stretched over it to keep flies or gnats, &c. from entering. This, of course, happens in a dark room, as also the previous operations of preserving and washing; the films should also be sheltered, even from light entering through a yellow glass window, or from a candle light.

The time of exposure should not be curtailed, for a full period will do no harm; about the same as for collodio-albumen plates is needed.

Between exposure and development any amount of time almost may elapse. Our experience does not, however, extend so far as to justify us in saying that when the plates are developed only after a lapse of months, they should receive the same amount of exposure as when they are developed immediately. A properly exposed plate requires about a quarter of an hour to develop, intensify, fix, and wash, and shows all details in the highest lights and deepest shadows, with the richest tones, and the most marked co-

trasts between light and shade. The development is conducted in the following manner (acid development) :—

		<i>g.—Developer.</i>	
No. 1.—Pyrogallic acid	...	...	7 grammes
Water	...	...	1 litre
Acetic acid	...	...	10 cubic cents.
No. 2.—Silver bath <i>f</i>	...	...	100 cubic cents.
Acetic acid	...	...	10 drops.

The plate is first moistened with distilled water, the same being either poured over the plate, or the latter immersed in a bath and then treated with the pyrogallic solution No. 1; after a few moments the latter solution is poured back into a developing cup, a few drops of No. 2 solution added, and the plate again treated with it. The picture appears, if it has been properly exposed, in about half a minute, or, at any rate, comes fully out within three minutes; and, on being further tried with a mixture of No. 1 and No. 2 solutions, attains its full vigour in a few minutes. The film is then washed as usual, and fixed with hyposulphite of soda or cyanide of potassium; it receives, of course, a good final washing. Should the result be lacking in vigour, it may now be further intensified with a mixture of the two solutions, but if this is necessary the film should be previously washed with more than ordinary care, in order to prevent the formation of a sulphide of silver precipitate, which must inevitably be produced if any hyposulphite be left clinging to the plate.

In the photographic operations to be undertaken at the transit of Venus, the acid development, with little addition of nitrate of silver, must be employed with this process, no increase in the lines of an image being produced except in the case of intensifying, and this is never necessary with the energetic action of the sun. Old and experienced photographers demand alkaline development, but a great drawback to the same is that it loosens and lifts the film. After drying the plates are warmed, and either coated with varnish *d*, or with that manufactured by Schering.

It seemed advisable to us to ascertain the behaviour of the albumen in this process, and with this view we coated plates with silver collodion, without addition of varnish, iodised them, washed them, coated them with uniodised albumen, as mentioned in our collodio-albumen process, washed again, and allowed the plates to dry, to be sensitised at some future time. Other plates we sensitised at once by washing over with fresh nitrate of silver solution (six per cent. strength), mixed with a little acetic acid. The plates yielded identical results, whether they were treated with the silver solution at once, or dried and silvered weeks afterwards. They worked rather more slowly than the varnished plates, but, nevertheless, gave excellent results. While thoroughly exposed plates, prepared by the collodio-albumen process, are of an olive-green tint, the image produced upon these films is, on development, of a violet-brown. Further experiments were then made with the process somewhat modified, the behaviour of the plates, without lac or other addition, being investigated. Some silver-collodion plates, without varnish, were iodised and washed, and then a portion of them sensitised at once, while others were first dried, and then sensitised in the silver bath *f*. We had here to do only with pure iodide of silver in collodion, without any other combination with silver, for the pyroxiline does not combine in any way. Upon these plates we were only able to secure very matt images, like those on unprepared paper; indeed, the minute quantity of shellac added in the process proved, in all our experiments, to be the cause of the brilliancy in the pictures, and of the permanent character of the film. The combination of silver and shellac, like albuminate of silver, takes the place of the free nitrate of silver in the wet process as sensitiser, betraying a tendency to absorb iodine.

Passing now to the aspect of the film under the microscope after exposure and development, we will give attention to

the particular nature of the network on the film. In the first place, it must be mentioned that the network in every part of the plate, after completion of every operation, is precisely the same, and occupies the same position on the plate as before its exposure to light. We have proof here, therefore, that the film is perfectly stable, and that it is especially fitted for the main purpose for which it is designed. From the character of the network, too, we are able to know whether we have added too much varnish to our collodion. The less the addition of varnish, the more delicate is the network formation, the finer is the film, but also the more liable is it to injury. By an addition of varnish (from one to six drops to ten cubic centimetres of silver collodion) the network is very regular; it is strongest where the collodion upon the plate is driest. Four to six drops of varnish yield a network which is still quite fine enough, and the permanence of the films leaves nothing to be desired, and there is material enough present for the production of a sufficient quantity of shellac and silver compound to obtain the highest amount of vigour in the picture. If more than six drops of varnish are added, the network becomes injured, and is unequal upon the film, being divided generally in the middle, and this circumstance is the more glaring the greater the addition of varnish. To a sharp eye this appearance of lines or shading is apparent upon the film, which appears to be corroded, or eaten through. On adding nine or ten drops of varnish to every ten cubic centimetres of silver collodion, nearly all the network, in the direction where the collodion has been poured off, appears split and broken—the splitting being very apparent in the middle. At the same time the net walls are very thick, the structure of the film very coarse, and every hair or fibre that may accidentally appear upon the film is surrounded with coarse particles. As the network betrays this appearance before exposure, the plates may be easily recognised on examination by transmitted light, and can be put on one side. In one and the same batch it can never happen, however, that some have a delicate and uniform network, while others have the latter phenomenon in too marked a degree; either the plates are all good or all bad. That they will not turn out of the latter kind need not be feared, if our prescriptions are explicitly followed. To be quite sure, it is best not to mix more than four or five drops of varnish with every ten cubic centimetres of collodion, for if a little brilliancy and intensity be sacrificed, still there is then no danger of producing unserviceable plates. It is well also not to employ a supply of collodion too long, when, from being poured on and off, it becomes thickened by evaporation.

One very particular advantage of this new process lies in the fact that the film, so far as our experience during the last year teaches us, remains perfectly stable, even when exposed continually to the action of a moist atmosphere, or frost and heat. The particles forming the film, which, under the microscope, appear to be of a most homogeneous nature, do not seem to be altered, when magnified sixty diameters, by any changes that may take place in the temperature or moisture of the atmosphere around. The particles always remain in their places, so that the image retains its primitive position upon the glass plate, and its outlines and measurement are not varied. The best and most reliable proof of this is furnished by our own microscopic productions, in which exactly the same position of the plate, shown by a cross scratched thereon, is maintained after development, fixing, and washing. These pictures convince every spectator of the unalterable nature of the network of the film. If, moreover, the measurement of the results is effected in an atmosphere of the same temperature as that in which the image has been produced, there can be no doubt as to the accuracy of the same, and the high scientific purpose of the expedition in employing photography would be answered.

## MEANS OF EXCLUDING CHEMICAL RAYS.

BY JOHN M. BLAKE.\*

I HAVE once before called attention to the value of bichromate of potash solution for this purpose. By its use we can obtain an excellent illumination, and at the same time it is very effective in stopping out chemical rays. Four years' experience in its use has confirmed my first impression as to its utility; but I can now give some further hints that may be useful.

My attention was first drawn to the properties of this solution by mention made of it by Mr. B. Ford (see *PHOTOGRAPHIC NEWS*, 1869, p. 451). He employed the solution, inclosed between two plates of glass, and was thus enabled to watch development through it when out of doors.

Soon after I had given the results of some experiments, made to determine the comparative value of this means of illumination, the matter was reduced to practice, and very little modification has since been found necessary in the original arrangement. In the first place, it is well, as involving less trouble and expense, to depend upon yellow paper, as heretofore, for the general lighting of the room—that is, when a window of sufficient size is available—but to have some means of darkening this readily when danger of fogging is apprehended. Then immediately opposite, and as near as possible to the place it is most convenient to hold the plate while developing, have one or two common cylindrical quart bottles filled with half saturated solution; each should stand upon a small circular shelf with raised edge, placed at the bottom of an opening in a thin board partition. White light should be completely excluded by tacking elastic woollen cloth, so as to press the edge on against each bottle, and also by blacking the bottoms if found necessary. The necks of the bottles should come just inside of the partition, the shelf being inclined for this purpose; thus arranged they can be taken out on cold nights, to avoid freezing. Glycerine or alcohol is not admissible as a preventative; it would reduce the chromic acid. Only solution made from clean crystals should be used. This apparatus will throw a bright light upon an object brought near to it, and its chief value will be for the critical examination of negatives during and after development. Few will undertake to light the whole room by this means, although it is easy to imagine what a non-actinic paradise is thus brought within the range of possibility.

In order to make the most of the small aperture that we do use, it is necessary that the light from the sky or snow-covered ground, &c., should not be obstructed from reaching the bottles. It will then pass through from all directions, as through a globe lens, though from an even larger field. The globular form of containing vessel will thus be found superior to the flat; but a cylindrical vessel is cheaper, and more easily replaced, while practice shows it to be little inferior to the globular form. Two one-quart bottles of bright glass were found equal to an eighty-ounce thin globular flask eight inches in diameter. The bottles can be placed close to an argand lamp, when preparing plates in an evening, and thus a powerful light thrown to a long distance, making drying racks and bath visible with an entirely safe light, while by a near approach a splendid light can be got for development. It is well, once in a month or two, to filter the solution, and wipe the inside of the bottles to remove any deposit that may obstruct the light.

Two four-ounce vials filled with nearly saturated solution gave a splendid illumination inside a tent of the Rouch form; one was placed in the top and received the skylight. When the sun was shining on one of the vials, but screened by tissue paper, a light was obtained that a photographer, from habit, would instinctively shrink from; but plates were prepared, drained, and developed, quite free from fog. The advantage of having such a light to develop by will strike any one on trial. It often happens in many mechanical

operations that a workman will accomplish much more work, and do it better, if pains be taken that he has a proper light by which to work. Employers often overlook their own interests by not recognizing this simple fact. Why should this be any the less true in the case of development, an operation requiring great experience and care, and attentive watching? In a proper light, the point where the last portions of clear glass are leaving the shadows, or the first symptoms of fog, can be readily detected. Who cannot recall experience in working in some black hole, where the operations have been pretty much reduced to the game of hit or miss, and you could only know what you had bagged, or what blunders you had failed to commit, on emerging into daylight? This is an extreme case; good work can be done if care is taken to profit by ordinary means of illumination. The use of the light through bichromate of potash solution, it is claimed, will enable us to make still another step in advance.

And now in regard to the reason of the superiority of this solution; the spectroscopist shows at once. If we start with a very dilute solution, we shall see that the transmitted light shows the spectrum in the red and yellow with undiminished brilliancy; while the green, and part way into the blue, are visible to a certain extent. As we increase the strength of the solution, the blue is soon cut off entirely, and with a strong solution, the portion of the spectrum that contains the active chemical rays is suddenly cut off from the middle of the green, while the red and yellow rays are transmitted with little loss of brilliancy. That portion of the green remaining adds to the illumination, while its chemical activity is almost nothing.

If we compare yellow pot-metal glass, just such as is commonly sold for this purpose, we find the light greatly diminished in the red and yellow, and while the transmitted light is thus robbed of its most valuable part for visual purposes, the spectrum can be traced far into the blue. A specimen of flashed yellow glass was found not to be superior to the other variety.

Certain varieties of flashed red glass make perhaps the most effective screen known; but there is the drawback that little light is transmitted, it being only a part of the red. Full sunlight may be allowed to fall, through a suitably chosen sample, upon a sensitive plate for several seconds without producing fog. Yet by the aid of the spectroscopist and direct sunlight, blue or violet transmitted light can be detected with little difficulty, provided we superpose a piece of green glass to cut off the glare of red light. A blue sun can be seen by simply looking through the red and green glass mentioned, with the addition of a piece of blue glass.

The utmost amount of light that can be transmitted by any possible medium can of course only approach the amount that falls upon it. If one medium transmits three times as much light as another, and has at the same time the advantage that a sensitive plate can be exposed to its full intensity thirty times as long without producing fog, it is reasonable to conclude that the former is ninety times more efficient. If we reason in this way we may take the above figures as expressing the relation of bichromate solution to yellow glass. If we choose, we can continue to dilute the solution until the same number of seconds' exposure to its full intensity will fog a plate, as when it is closely approached to the yellow glass window. Now our solution will not admit very much more light than it did before, since when strong it transmitted the greater part; still there is a marked increase in the light, and it looks so white, that one at first can hardly credit that a plate will stand as good a chance of developing up clear as before the comparatively dark yellow glass window. A landscape was taken in ten minutes through a yellow glass by means of a portrait lens.

A word in regard to the poisonous properties of bichromate of potash. A case is reported (see Taylor on Poisons) of death in five hours from accidentally receiving a small quantity of solution into the mouth in using a siphon.

### THE PHOTOGRAPHIC SOCIETY.

On Tuesday next the members of the Photographic Society will have an opportunity of expressing an opinion in relation to the laws by which they have been governed during the twenty years of the Society's existence. It affords matter for curious reflection to note that the society has passed through three septennial periods, has done much work, has seen much change, and, after serious decline and pecuniary embarrassment, has again emerged from the cloud into full prosperity: solvent, active, vigorous; all this time existing under a code of rules confessedly clumsy in structure, involved and obscure in meaning. We are forcibly reminded of Goldsmith's lines (or rather Johnson's lines on Goldsmith's poem), which suggest that of all the ills that mankind or society can endure, how infinitesimally small is the part "that laws can cause or cure"! It is probable that neither the efficiency, the prosperity, nor the adversity of the society was influenced one iota by the laws in question. When the society was, indeed, at its worst estate, but a few short years ago, no one dreamed of imputing the difficulties to the laws, and without altering the laws, by the close application, and the devotion of time and money by the council during the last few years, the society has thoroughly recovered its solvency and vigour.

A time of prosperity is, however, in many respects pre-eminently well fitted for revision and re-organization of laws. It is not in the midst of the storm that a ship is overhauled for re-caulking, re-trimming, or repairs. In regard to the laws of the society, few persons will be disposed, we imagine, to affirm that they are models of perfection. Many years ago, when the society was in a state of comparative infancy, the Chief Baron referred, in his seat in the presidential chair, to the necessity of revision, and at that time such revision was attempted: new rules were draughted, and a few copies were printed; but, after careful consideration, they were not adopted, and the matter was put off until a more convenient period. Thirteen years ago, some correspondence on the needed revision of the laws was published in the PHOTOGRAPHIC NEWS, and, according to one correspondent, unless the laws were amended, the extinction of the society by the superior energy of rival societies was inevitable. But the society was not extinguished, whilst some of those whose superior energy was the base of comparison have long ceased to exist. There has been a persistent apathy in the members of the society, in relation to the rules, which must be very disheartening to those who believe earnestly in the importance of reform. But the machinery now set in motion must issue, we imagine, in a complete revision of the laws, and it only rests with the members to make

the provisions of these laws as equitable and as liberal as the most prudent reformer can desire.

It may be well briefly to state the actual state of affairs. There will be two meetings at which the machinery of reform can be put into operation—the special meeting, and the annual general meeting. For all practical purposes a special meeting was unnecessary, as, by the provision of existing laws, any desired alteration can be made at the annual meeting, due notice having been given at the previous monthly meeting; and notice of motion for a committee to revise laws was given at the meeting in January. But the special meeting, having been "requisitioned," was appointed by the council, for convenience, on the same night as the annual meeting, giving it precedence, however, as regards the hour of meeting. The requisitionists have given notice of motion for the amendment of Rules V. and VII. Now, according to the law which governs special meetings, the business of which due notice is given can be transacted, and that only. The amended rules of the requisitionists can be accepted as they are, or rejected; but they cannot at that meeting be modified. To avoid the absolute necessity of either alternative, the council have given notice of an amendment which comprehends much more than the motion of the requisitionists, as it invites the co-operation of the society in a complete revision of all rules. In effect, this is practically the same as the motion of which notice was given by Mr. Hughes, and might be adopted by that gentleman, without impropriety, as his own. But it became necessary to submit it at the special meeting, for the purpose of avoiding the necessity of the alternative to which we have referred. Many members may not approve of the resolutions of the requisitionists as they stand, but may, at the same time, desire reforms. The amendment of the council meets the case of such members, and permits effect to be given to their wishes at the special meeting. The amendment of the council possesses the advantage of placing that body in a fair position in relation to the society, and, by suggesting that the committee should consist mainly of ordinary members of the society, shows the groundlessness of the charges made by some, to the effect that they were opposed to reforms.

There is, moreover, a much more potent reason for a revision of all rules in such a case than at first appears. Apart from the fact that many other rules need reconstruction, there arises another consideration as important to the requisitionists as to those who may not hold the same views. If the resolutions of the requisitionists were adopted, the new laws would be antagonistic to some of those left unrevised. It is a very difficult thing to tinker a code of rules by the modification of one or two of them, leaving untouched the rest, without getting into confusion. We have not examined the relation of the proposed amendments to the laws throughout; but at first glance we notice that, amended, Law VII. is opposed in one of its details to the very first provision of the existing laws which would be left untouched. In this paragraph it is provided that, besides president and vice-presidents, the business of the society shall be conducted by eighteen members of council and a treasurer. No amendment is proposed to this; but in the proposed new Rule VII. it is provided that the treasurer shall be selected from the eighteen members of council. The first provision in existing rules states that the ordinary members of the society shall elect their treasurer. In the proposed new rule the Council are to elect the Treasurer. Now, as these existing provisions remain unaltered according to the notice of the requisitionists, and their new Rule VII. contravenes them, the passing of such new rule would issue in a code of which the first provision or preamble contradicts what follows. There may be other contradictions, as we have only glanced to ascertain whether the new rules were in harmony with the preamble of the code of which they will form part. The first impulse of many readers will be to

exclaim, "But why not also alter the first provision to secure harmony?" Simply because, as we said, no alteration can be made at the special meeting without due notice; and to secure harmony in this, and possible other points, another meeting, with due notice of all the modifications desiderated, must be given.

For the convenience of our readers, we print on another page the existing rules and the proposed modifications.

The proposed new laws are, we think, open to objection in two or three points—chiefly on the score of insufficient liberality and breadth of spirit. It is proposed that all officers shall be elected for three years, and that at the end of that time the retiring members shall be disqualified for re-election until after the lapse of twelve months. Both provisions appear to us to be bad. A three years' undisturbed tenure of office is much too long for one who may prove unsuitable for the position, either from indifference to, or unfitness for, its duties; whilst disqualifications for office at the end of three years, no matter how admirably its duties are fulfilled, is surely a short-sighted provision. Take the case of president, for instance: An efficient president is most important to the well-being and comfort of a society, and, once secured, should not readily be given up. One of the most efficient and happy of all the photographic societies is, by common consent, the South London, and the Rev. Mr. Statham has presided over the society ever since its commencement fifteen years ago. His loss would be regarded as a calamity by every member of the society, and it is more than probable would have issued years ago in the extinction of the society. Yet by such a rule as that proposed his retirement from office would have been imperative. With a yearly tenure of office, every officer would be liable to retirement, but eligible for continuance, so that inefficient officers would be easily got rid of, and efficient ones retained as long as the society desired. To prevent changes so sweeping as to interfere with the business of the society we should provide for the retirement every year of one-third, their selection and replacement being left entirely to members of the society. By this method there would always be two-thirds of the council familiar with its business left in office; but, as any one of the whole number might be retired by the voice of the society, none would have more than an annual tenure of office. The services of each officer, in the shape of attendances at council, reading of papers, committee work, &c., might be placed within the knowledge of the members as a guide to election.

Another very undesirable provision in the proposed new rules is the nomination of candidates for office in open meeting by proposing and seconding a month previous to the election. It would involve the possible devotion of the January meeting, as well as the annual meeting, to business purposes, and in any case a certain amount of invidiousness and discomfort might easily be involved in open pitting of a series of candidates against each other. The present system, which is clearly open to some objections, is better than this, as it merely demands that lists of nominations shall be handed to the secretary in writing. Further, the personal proposing and seconding of candidates ignores another very important point in connection with a society like the Photographic Society of London. Of the three hundred members of whom it consists, probably upwards of two hundred reside in the country, and can rarely or ever attend the meetings. In order to secure any voice in the government of the society to which they subscribe, they would be under the necessity of coming to London to attend two meetings of the society, at which routine business, rather than photographic matters, would occupy a large portion of the proceedings.

And this brings us to another very important question for which no provision is made, either in the old or new rules—the voting of country members. In any satisfactory code of rules it seems to us that such provision should

form an important element. It would not be difficult to establish a system of employing voting papers combining the principle of the ballot, and admitting of non-personal voting. The proxy system, as usually employed, is open to serious objection, as it permits facilities for a governing board, or a combination in a society, to organize to secure a number of proxies by which any proposal might be carried or swamped. But if voting papers were forwarded to all members, containing all nominations forwarded in writing to the secretary, and these voting papers were returned to the secretary, who should deliver them, still sealed, into the hands of scrutineers appointed at the annual meeting by the members, no such difficulty need exist, and country members would possess their legitimate voice in the management of the society. We here briefly indicate a possible method; but that some method with such aim should be adopted must, we think, commend itself to all just thinking men. The mode of securing the best results in such matters will, no doubt, be best devised by a well-chosen committee; and as they would report to a general meeting, the whole question will, doubtless, come before the society before any new code can be adopted.

#### ACCELERATION BY LIGHT.

The method to which we called especial attention in our last, of exposing a sensitive plate to white light passing through opal glass for a few seconds, as a means of shortening exposure, has been verified by some of our readers in a most satisfactory manner. We have been favoured by Mr. Samuel Fry with a series of negatives showing the results of comparative exposures on two halves of the same plate, on the same subject, in which one half was exposed in the ordinary way, and the other half had a previous exposure of a few seconds to light through opal glass. Nothing could be more striking and satisfactory, a manifest saving of from half to two-thirds of the exposure on the sitter being saved. It is unnecessary to describe every plate, but, as an illustration, we mention the details of one before us. On one-half of the plate we have an image, decidedly under-exposed, with a twenty-five seconds' sitting; on the other half an image of the same sitter well exposed, with twelve seconds' sitting, having had previously four seconds through opal glass. Mr. Fry informs us that in a letter just received from Mr. Slingsby, that gentleman informed him that in producing some of his large negatives during the last few days he had tried this method, and obtained as good a negative in twenty seconds with the aid of opal glass, as he did in fifty seconds' exposure without it. *Verbum sap.*

#### GELATINO-BROMIDE OF SILVER.

Our attention has been called by Mr. H. A. Kennett to some most important details of the discovery in connection with gelatino-bromide of silver which he has recently patented. The various difficulties which have seemed to surround the use of gelatine emulsions hitherto have precluded much idea of the supersedure of collodion by gelatine. To begin with, gelatine is a substance of variable and uncertain physical quality. It is very unstable when in solution, and almost impossible to keep. Films prepared with an emulsion of gelatine were apt, in some cases, to soften seriously, or even dissolve, when immersed in water previous to development, and in others obstinately to repel the water. These and other difficulties rendered its use instead of collodion unattractive to the majority of photographers, amateur or professional. In the project of Mr. Kennett all these difficulties seem to be eliminated. He has succeeded in a method of preparing a suitable gelatine which can be sent out to photographers in a dry state, containing, however, the sensitive bromide of silver. All that remains to the photographer is to add a stated proportion of warm water to a few shreds of the sensitive gelatine, and in a short time he will have an emulsion ready for use. A plate coated with this and exposed

whilst wet is said to be as sensitive as an ordinary wet collodion plate. A plate coated with the emulsion and dried is, without further preparation, a dry plate which will keep for months, and require an exposure of less than twice that required by a wet plate. There is, we are told, equal immunity from risk of the gelatine softening and dissolving, and from its repelling the water or aqueous solutions used in developing. Surely the prospect of being able to obtain a solid sensitive substance, keeping indefinitely, ready for use at a few minutes' notice wherever warm water can be procured, and giving quick and excellent results, must be a very attractive one to photographers.

The results themselves, several of which Mr. Kennett showed us, are certainly perfect. The singular delicacy of the image in a film so homogeneous and free from structure as gelatine can be easily understood, and there is that rich fine quality which results from the densest deposit, retaining a slight translucency, instead of being quite opaque. The colours can be varied at will, and in those we saw ranged from a fine black, through various tints of olive and brown, to a deep ruby. The images were free from defects of any kind.

The method which Mr. Kennett has worked out appears to be very simple as well as promising. Having made extensive arrangements for a supply of the right kind of gelatine, it is dissolved with the bromide salts, and this done, the nitrate of silver in equivalent proportion is added, and at once forms the emulsion. A little excess of either salt is not important, as it is next necessary, not only to get rid of any such excess, but also of the nitrates of potash or other base formed in the double decomposition. Various methods have been proposed and tried for effecting this, dialyses having been one of the most promising. Difficulties and impossibilities were found attending most of the methods tried; but at length Mr. Kennett devised a plan of simple washing which completely effected the purpose. The emulsion after this is dried in thin sheets, and then cut up into shreds, which simply consist of gelatine and pure bromide of silver, for use as we have described. Alkaline development is of course employed.

At present we must confine ourselves to this brief statement of the promise of the project, which seems based on legitimate premises. Verification in practice rests with the future; but as the facilities for such verification will very shortly be placed before photographers, the promise is, we think, sufficiently tempting to deserve careful attention and investigation.

#### SPIRIT PHOTOGRAPHY AGAIN.—IMAGES FROM INVISIBLE RAYS.

THE *Examiner* of last Saturday contains a long communication from Mr. James Thornton Hoskins, on some recent investigations in connection with spirit photography made by himself and a friend. The investigations were made at the studio of Mr. Hudson, of Holloway Road, whose name is familiar to photographers as connected with "spirit photography." Being personally unacquainted with photography, he says:—

"I took with me a friend, Mr. Noyes, of the United University Club, a gentleman who has photographed extensively in Egypt and Syria, and who has therefore sufficient experience of the art to be confident of being able to detect any attempt at fraud, if admitted to the photographer's sanctum. Mr. Noyes, I should premise, is a gentleman of good social status, whose honesty is above suspicion. On our arrival at Mr. Hudson's, we met, by appointment, Mrs. Olive, a trustworthy medium, or person gifted with a sensitive negative-magnetic temperament, and thereby enabled to facilitate communications with psychic agents, whose corporeal forms, being more or less fluidic and etherialized, are invisible to the sense of sight in its rude elementary physical condition. After some preliminary conversation, we all passed through the garden into the

glass-house, at the extreme end of which, and entirely partitioned off from it by a canvas screen immediately behind the sitter, is a closet, intended to accommodate the medium. When the plates were prepared, and all was ready, Mrs. Olive left the glass-house and entered this closet, so that it would have been physically impossible for her to come within the range of the instrument. I was taken five times. On the first occasion, I persisted in the wish that I had mentally expressed on the preceding day, *i.e.*, for the presence of two departed relatives, the result being that two very indistinct shrouded forms appeared on the negative, one on either side of me. Not being particularly satisfied, as the features of one were entirely concealed, and those of the other but dimly visible, I sat, or rather stood, again. The next three attempts were complete failures. But on the fifth and last sitting, I silently wished for a manifestation by one spirit only. There then came out, in accordance with my desire, a good, though not very strongly-marked, likeness of my mother, who quitted this sphere in the winter of the year 1862."

Mr. Hoskins seems aware that in the statements just made he has tested the credulity of his readers, for he proceeds:—"Doubtless many who have read thus far will straightway suspect imposture on the part of Mr. Hudson. They will not unnaturally recall to mind instances of 'double exposure' and other trickeries. But the fact of this manifestation having taken place under strict test conditions is of itself, setting apart various other important considerations, a sufficient answer to that objection. Mr. Noyes was admitted to the dark room. He examined the plates used in the process sufficiently closely to be able to recognize them, saw them cleaned, inspected the camera and slides, placed the sitter, focussed the instrument, and superintended the processes of collodionizing and sensitizing the plates; remained in the operating room during the whole process, saw the plates taken out of the slide, watched with me the process of developing the pictures, and saw the portraits emerge simultaneously with the portrait of the visible sitter."

The explanation which Mr. Noyes gives to his friend, and which is quoted in the communication, is one ingenious blending of science and transcendentalism:—

"Those who are new to the subject may be inclined to scoff at the idea of being able to photograph an object invisible to the human eye. Good spectroscopists, however, know by experience that the camera will register outer rays of the spectrum, which, though invisible to the physical eye, are chemically potential. Indeed, they are aware that if a room be illuminated by prisms so arranged as to cut off the violet rays, the resulting light, though almost undiminished in brilliancy, will hardly act on the chemicals; whereas, by an arrangement which admitted the chemical rays and excluded the light rays, it would, in all probability, be feasible to produce photographs in a dark room. It would seem, therefore, by no means incredible that a more thorough acquaintance with the laws of light than we at present possess should enable spirits, invisible to ordinary vision, to render themselves visible to the camera by some occult concentration of the chemical rays on the magnetic envelope or spiritual body—the *nephes* of the Book of Genesis, or *perispirit*, as it has been called by French Spiritualists—and which can encrust itself by attracting quasi-material particles from the magnetic emanations of certain media suitable for the purpose—emanations which Reichenbach long since proved to be visible to sensitive organizations. Reichenbach's evidence has been disputed, but I have recently obtained unimpeachable independent testimony to support it; it not only helps one to understand the theory of Spirit Photography, but helps to explain the occasional materialisation of spirit forms to an extent which renders them visible to the physical eye. Ghosts will soon cease to be supernatural."

## Critical Notices.

**INSTRUCTIONS IN PHOTOGRAPHY.** By CAPTAIN ABNEY, R.E., F.O.S., F.R.A.S. (London: PIPER AND CARTER.)

We noticed some time ago an edition of this work prepared by Captain Abney, as Instructor in Photography at the School of Military Engineering in Chatham, for the use of his classes. We then expressed our regret that an instruction of such pre-eminent excellence should be confined to private circulation. We are glad to announce that a revised and extended edition has now been issued for general circulation. Captain Abney's manual is, in some respects, unique in its class, in character as well as excellence. There is one feature especially valuable, which we have found in none other. All the instructions, which are as simple, lucid, and easy to apprehend as they are accurate, are accompanied by explanations of the *rationale* of the operations to be conducted. This, which might at first sight seem confusing to a beginner, is, in reality, not so, as the instructions can be read, understood, and followed quite independently of any attention to the statement of the reactions involved; and when the practical points have been mastered, the work can be again studied with advantage for information as to why such and such results follow given operations. The book is singularly valuable, moreover, in its completeness, and in that completeness arising out of the practical experiences of a skilled worker in many varied branches of the art; the instructions are not, therefore, the work of a mere compiler. For example, there are several most important chapters on photo-mechanical printing processes, a branch on which the author is peculiarly fitted to speak. Dry plate photography is still more exhaustively treated, and with just the same practical authority. The work is, in short, the most comprehensive and trustworthy guide which has ever been issued, within the same compass, in connection with photography, and will be consulted by experienced workers and beginners with equal advantage.

### ON A NEW STUDIO.

BY S. FRY.

The Editor was good enough to insert a short note from me, a few weeks since, on the subject of taking large direct portraits. I then made some remarks on the best kind of studio and lighting, which seem to have attracted much attention, if I may judge from the number of requests I have received for further information.

I would first remark, that I see at the last meeting of the South London Society, Mr. B. J. Edwards, following the lead of Mr. Croughton, made remarks implying that it was well known that the difficulties of large portraiture were almost inseparable from the exposure required, and that enlargement from small negatives is the only proper way.

Please allow me to remind photographers that, great and valuable as are the advances made of late years in enlarging, the improvements in large direct work are, to say the least, quite as great. The last Exhibition showed very large direct photographic portraiture, from every part of England, of rare excellence, and quite free from coarseness or exaggeration, and abounding in artistic merit. No enlargement has yet been shown possessing the depth and richness of tone of direct negatives. This is not merely opinion or dogmatism, but was abundantly proved at our late Exhibition.

I desired last year to build a new studio. Ten years had elapsed since mine was erected, and neighbouring premises had encroached upon my light, and my exposures were doubled. I had plenty of room to build, and uninterrupted north light, and the great thing was to find the very best system. I determined to inspect the best and most successful studios in England, and have to offer my best thanks to Messrs. Robinson, Slingsby, Sarony, and Cooper,

and several others who gave every facility for the purpose. The result is, a studio of extraordinary rapidity, and giving the finest modelling imaginable, with the simplest possible arrangements of blinds. The side-light is low (six feet only), and the height to top of roof eleven feet; the north side has glass, except five feet at each end; the south side is entirely dark. The principal features are the low side, and very large steep glass roof; this gives the exact amount of side and top light which is wanted. Either end of the room can be used, and at a moment's notice, and the effects differ in no way.

During this last winter the exposures have been ordinarily insignificantly short, and babies and dogs have been, as required, taken almost without interruption.

If any one believes there is any real difficulty from length of exposure in taking very large direct portrait negatives, I shall have great pleasure in demonstrating the opposite. In addition to the advantages of light that I have referred to, may be named a great range of facilities for cooling in summer and warming in winter. For the former, the side sashes lift completely away, leaving free ingress for air, and lower boards at the upper angles keep the upper part cool. Last year the side of the room was thus open to air for all the summer and autumn months, completely getting rid of the stuffy heat so often felt in studios.

For warming in winter, three hundred feet of four-inch pipe pass through the ten rooms used for business, keeping at all times a genial warmth, and saving all the troubles of stoves or fire-places. The cost of the furnace averages thirty shillings per month only. The pipes pass through the developing room, and are thus of especial use, forming, also, in the studio, a hot cupboard, of great value for warming baths and other solutions, drying negatives, &c. Some time since, various plans for warming studios were described; but as a separate stove would be required for each room, the expense would be very great.

### MIXING SOLUTIONS FOR PHOTOGRAPHIC PURPOSES.

BY J. C. LEAKE.

THAT there is matter of more importance than meets the eye, at the first glance, in Mr. Warner's paper on the use of hot water in photography, published some weeks ago in these pages, there can be little doubt. We are not at all prepared to accept his statement that the use of hot water will at all times keep us out of it, by rendering all chance of failure impossible, nor to accept his theories without question. Yet it must be granted that he deserves the thanks of all for calling attention to a method of working which has proved so successful in his hands. But the question at once arises, What is the reason of this success? It must be evident to all that Mr. Warner's theory is erroneous, and that the mere boiling of the water does not, as he supposes, eliminate either all the organic matter or free it from oxygen, &c. If boiled for a considerable period—say, half or three-quarters of an hour—"hard water" is freed from carbonic acid, and carbonate of lime, if present, is deposited. In some cases, where the water is very "hard," to do this is, doubtless, an advantage; but in the water as supplied by most of the most London companies we have not, in our own practice, found this precaution necessary. Could we depend upon the distilled water supplied by dealers, we should probably employ this for the bath; but, on the whole, our experience has been that for all practical purposes that ordinarily employed for household purposes is sufficiently pure. Of course, there is a slight precipitate when this is mixed with the nitrate of silver, but this is of no importance (if it be not an advantage), as it can easily be filtered out.

It will, of course, be asked, of what advantage can it be that a precipitate is formed? And we reply, that we think that in falling, many impurities are carried down by the precipitate, and, consequently, the bath works not only more rapidly, but gives better negatives. One fact,

however, is worth many theories, and we can confidently state that our experience has been decidedly in favour of baths made with ordinary water rather than that termed "distilled." What, then, is the real cause of Mr. Warner's success? We believe it to consist simply in this: *that by the use of hot water he makes perfect solutions of his chemicals.* This idea will probably raise a smile with many photographers, but we have facts which we think sufficient to prove the correctness of our theory.

Everyone who has worked the collodion transfer process knows that one of the most tiresome and frequent causes of failure is the appearance of small opaque spots during the development. We, too, have had our share of these, and, after a long and useless search for their cause, we found only one source from which they could reasonably be supposed to arise. This was undissolved particles of pyrogallic acid. Now, to test this fact we set aside the ordinary solution, and mixed some by dissolving the acid in hot water. This at once freed us from our trouble, and, naturally enough, we concluded that we had discovered the cause.

But hot water cracks glass bottles and measures, and is otherwise troublesome; so, instead of this, we employed methylated spirit as a solvent for the acid, and with such perfect success that we have not, since adopting this method, had a single picture which has not been entirely free from this troublesome defect.

These experiments, of course, set us wondering as to the other solutions employed; and, as the result of very many carefully conducted operations, we arrived at the conclusion that many or most of the defects in our work are caused by an imperfect solution of the chemicals employed.

The remedy is, of course, obvious. We may use hot water for many of our solutions, or adopt other means if we prefer it; but our aim must be to perfectly dissolve every substance which we have to employ.

The plan which we have found to possess many advantages is the following:—We make the whole of our solutions in a concentrated form, and, for the sake of simplicity, of such strength as to require diluting with ten times their bulk of water before use. Thus, the silver "stock solution" is made by dissolving 750 grains of silver in two ounces of water; the iron developer, by dissolving 1,000 grains of iron in five ounces of water. The pyrogallic acid solution, either for transfers or redevelopment, is made by dissolving 100 grains each of pyrogallic and citric acid in five ounces of methylated alcohol. To each ounce of these solutions is added, for use, ten ounces of water, and thus we have always at hand a simple, easy, and rapid method of making up as much solution as we require, without the constant trouble of weights and measures. Of course, to the iron developer we must add the required quantity of acetic acid and alcohol, but these are variable in quantity, and no proportions can be given.

The toning bath for prints may also be made in the same manner, and if it does not work better, it is, at least, a simple and effective method of mixing, and one which renders the tired and busy photographer less subject to the temptation of employing the "rule of thumb" formula.

Now as to the result. Since we have adopted the above system we have obtained pictures which are absolutely free from pinholes or spots of any description, while the ease and simplicity of working have been greatly increased. In no case have we found it necessary to filter the developers. If the stock bottles are kept tolerably full, the few ounces of solution required can be decanted without disturbing the sediment, and, if added to clean water, will be found to be clear and bright. In making up the stock solutions, either hot or cold water may be employed, but the latter will usually answer perfectly.

The advantages of this method of working we believe to rest in the fact that, on account of the time allowed to elapse between the mixing and use, a perfect solution takes place; and we think, further, that this is all Mr. Warner effects by the use of hot water. In conclusion, we would

remark that on no account should the stock solution be used until it has stood at least twenty-four hours, if the full advantage of the system be desired.

### MORE ABOUT ENLARGING.

BY GEORGE CROUGHTON.

MORE about enlarging. There are many little things I have noticed in my every-day practice which could not be put into such a paper as I read before the South London Photographic Society, but yet are worth knowing, in relation to enlarging—bits of practice which probably are known to many, still they may be useful to some. I think it is a great mistake, when one has to describe a method of doing anything, to omit little details with the idea that they are known to every one: they may be just the rock upon which the tyro will split.

It is no use thinking that a mixture of all your old dis-used baths will do for enlarging; the bath must be in the best condition; small defects, which would pass in an ordinary photograph would utterly ruin an enlargement. Pinholes must be avoided like *poison*, as a crop of pinholes upon the transparency will cause the negative to be covered with a number of opaque spots, which upon printing will make your figure look as if in a snow storm. I find it best to keep the bath slightly acid with nitric acid; I put three drops of strong nitric acid to my bath of about two hundred and sixty ounces. Any ordinary collodion will do; I am using a mixture of Mawson's and Hggon's in equal parts.

I am often asked how I avoid stains and streaks with the long exposures. I think a great cause of stains of every sort is putting the plate into the bath before the collodion is thoroughly set. Let your collodionized plate rest upon the dipper at least one minute before lowering it into the bath; then do not plunge it in, but lower it very gently. Put clean pieces of blotting-paper in the corners of your carriers, raise the plate *very* slowly from the bath (not before it is thoroughly well coated, and every trace of greasiness gone), drain and wipe the back with a pad of blotting-paper, and you will never have either streaks or matt silver stains. You may be sure if such stains do occur after all these precautions that there is not acid enough in the bath.

Pyro has been recommended by a recent writer in the News for intensifying the transparency instead of the bichloride of mercury. I use the latter in preference, because I think the pyro piles up a somewhat coarse deposit of silver in greater proportion on the blacks than the half-tones. The bichloride of mercury changes the colour all over in a more equal manner. I find no difficulty in its use of the strength I named, viz., half-an-ounce to twenty ounces of water. I flow it on while the plate is flooded with water, and the action takes place pretty equally, but if I see one place not darkening so quickly as another, I pour it off, and pour it back upon the part that requires it; but if the bichloride of mercury is put into a flat dish, and the transparency put into it, there is no fear whatever of unequal action.

Having said so much about exposing the transparent positive enough, I had forgotten to mention the fact of a long exposure being necessary for the enlarged negative. The class of enlargement with which we are so familiar, the black and white coarse-textured things with ropy hair, are the results of under-exposure. Any one who has done much at copying will know that if they give a full exposure and short development, they can get rid, almost entirely, of the texture of the paper. So it is with enlargements: texture can be quite got rid of by a full exposure, and the stoppage of the development at the right moment, which can only be ascertained by experience.

There is, as Mr. Edwards pointed out, a great power in the hands of the enlarger in the way of diffusion of focus; but even that must be done very carefully. I find that if I try to get this diffusion by turning the camera in—that is, by moving the ground-glass nearer the lens—I do

not get such an even diffusion as by moving it further from the lens. I sometimes resort to the dodge of taking out the stop during the exposure, which answers well for some negatives.

I find a very great advantage in having my developer in two solutions, one of iron and the other acetic acid and spirit. If it should happen that I have given too long an exposure for my transparency, and it makes its appearance directly I put on my developer, I have only to add some of the solution of acid and spirit, and the development is prolonged and put more under control. The same in developing the negative, if the original has been too soft and thin, and the transparency from it is lacking in brilliancy, I use less iron and more acid; if, on the contrary, the original is hard, I use more iron and less acid.

#### RULES OF THE PHOTOGRAPHIC SOCIETY.

For convenience in reference, we here reproduce Rules V. and VII. of the Photographic Society as they now stand, and the rules which the requisitionists propose to substitute at the special meeting to be held on Tuesday evening next:—

##### OLD RULE V.

"The business of the society shall be conducted by the president, three vice-presidents, treasurer, secretary, and the remaining eighteen members of council. At all meetings of the council five shall be considered a quorum. One of the vice-presidents, the treasurer, together with five other members of council, shall go out of office annually, all, or any, of whom shall, however, be eligible for re-election.

"The council shall hold their meetings at such times as they may appoint. The ordinary mode of decision of questions before the council shall be by show of hands, unless a ballot shall have been demanded. Any member who may be personally interested in the question before the council shall retire during the consideration and discussion of the same. The council shall also prepare, and cause to be read to the annual general meeting, a report on the general concerns of the society for the preceding year."

##### OLD RULE VII.

"All officers of the society shall be annually elected, with the exception of the secretary and such members of the council as may not go out of office by rotation or otherwise. The mode of their election shall be by ballot. The council at the ordinary meeting in December in each year shall declare the names of the members of council whom they recommend to retire, and lay before the society the names of those whom they have selected to supply their places. They shall also declare the names of the other officers they recommend for re-election, and cause a list to be suspended in the meeting-room. In the event of any member of the society being desirous of proposing other names than those recommended by the council, a written list of the same shall be delivered to the secretary at or before the ordinary meeting in January; and the same shall be read from the chair, and publicly suspended in the society's room, with the list recommended by the council; and no member shall be eligible for election into the council unless he shall have been proposed in the manner and form above specified."

##### NEW LAW PROPOSED TO BE SUBSTITUTED FOR OLD LAW V.

"The business of the society shall be conducted by the president, three vice-presidents, and eighteen members of council. At all meetings of the council five shall be considered a quorum.

"The president shall be elected to serve for three years, and shall not be eligible for re-election until after a lapse of one year.

"The vice-presidents shall be elected to serve for three years; each year one of them shall retire from office (the rotation being by seniority), and shall not be eligible for re-election, or to serve as a member of council, until after a lapse of one year, but shall be immediately eligible for the office of president.

"The members of council shall hold office for three years; one-third shall retire each year by seniority, and shall not be eligible for re-election as members of council until after lapse of one year, but shall be eligible for the office of vice-president or president without waiting such interval of time.

"The council shall hold its meetings at times to be determined by itself. Questions before the council shall be settled by show of hands, unless a ballot is demanded. Any member personally interested in a question under the consideration of the council shall retire during the discussion. The council shall prepare a report on the general condition of the society, for submission to each annual general meeting."

##### NEW LAW PROPOSED TO BE SUBSTITUTED FOR OLD LAW VII.

"At the ordinary meeting of the society in the January of each year the secretary shall declare the names of the vice-president and of the members of council who retire from office, shall state the fact when the term of the president's holding office expires in that year, and shall invite the members present to nominate their successors, every name being proposed and seconded in open meeting. The list of nominations shall then be publicly read by the secretary, and a copy of the same shall be sent to every member of the society before the next annual meeting in February.

"The election for all vacant offices shall take place at the annual general meeting in February. If there be no more persons nominated than are required to serve, those persons shall be held to be duly elected. If there be more than one nomination for the office of president, or more than there are vacancies for among the vice-presidents and members of council, an election shall be held for each vacancy, and the person who has the highest number of votes in each case shall be held to be duly elected.

"If vacancies occur by death, resignation, or other cause in the office of vice-president or members of council, individuals shall be elected at the annual general meeting to fill the vacant places, and shall serve the offices subject to the condition of retirement by seniority that would have applied to the persons whose seat they fill.

"The treasurer shall be elected annually by the council from among its own members.

"The secretary shall be annually elected by the council; and if not already a member of council, shall be entitled to an *ex officio* seat at the board, without a vote."

### Correspondence.

#### DIRECT PICTURES *VERSUS* ENLARGEMENTS.

DEAR SIR,—Allow me to call your attention to a typographical error in my letter on "Direct Pictures *versus* Enlargements" in the NEWS of last week, in which, by the change of two letters, I am made to affirm the truth of a measure I wish to deny: "That eight inches is much *about* the average of the human face, taken from the bottom of the chin to the parting of the hair, is beyond question?" The word *about* should be *above*. Five inches *focus* also at the end of the paragraph should be five-inch *faces*. As I write with a quill pen, I can easily understand how such little mistakes originated.—Yours respectfully,

R. W. ALDRIDGE.

#### VOTING AT THE PHOTOGRAPHIC SOCIETY.

SIR,—I have just received from the Secretary of the Photographic Society a post card stating that a voting paper would be sent in the course of a few days to all those members who had paid their subscriptions, as it was the desire of the Council to provide all *bona fide* members with the means of voting at the next annual meeting.

Now, I am an exceedingly *bona fide* member, having compounded for the amount of my subscription years ago; and I am also very much interested in the affairs of the Society, and consequently anxious to vote at the general meeting; but this I am effectually prevented from doing. The terms stated on the post card are, that the voting paper is to be delivered "personally" at the meeting. This I cannot do. I cannot, even for the love I bear to the Society, and my desire to promote its best interests, give up my business for the time necessary for a journey to London. I have heavy work in hand, and no one of sufficient confidence I can leave in trust of my affairs. If I could find any one who would take my place for a day or two, I should not at all grudge the eight or ten pounds which it would cost me to travel up to London and back, including the usual hotel bills, &c. Do you not think that the voting papers of *bona fide* members should be receivable by post?—Yours truly,

A BONA FIDE MEMBER IN THE NORTH.

[The existing laws are silent on the subject of proxy voting; and although the adoption of proxy voting in the absence of any provision on the subject would not be without precedent, the Council, it appears, hesitate to adopt a new course at such a time, especially as such a tendency to misestimate their motives has been manifested in some quarters. Those interested in the question should see that in the revised code of rules provision is made for all members recording their votes, whether resident in town or country.—Ed.]

## Proceedings of Societies.

### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Tuesday evening, the 27th ult., at the Free Public Library, William Brown Street, Mr. R. C. Johnson in the chair.

The minutes of the last meeting were read and confirmed, and the newly elected President, Mr. P. Mawdsley, then entered on the duties of his office.

The PRESIDENT apologised to the members for not having prepared for them the usual address, but, as there was sufficient business for the evening, no doubt they would excuse him.

The Rev. Usher B. Miles was elected a member of the Association.

A vote of thanks was passed to Mr. G. W. Wilson, of Aberdeen, for his kindness in lending his negative, "The Path by the Loch," for the purpose of an autotype enlargement for the presentation print.

Mr. H. GREENWOOD sent for inspection some exceedingly interesting specimens of minute Dallastype printing, and an extract from a communication received from Mr. J. T. Taylor, explanatory of the method by which he (Mr. Taylor) had obtained similar results, was read by the Secretary.

Mr. J. A. FORREST presented to the Association a pair of Edwards's combination printing-frames, for which he received a hearty vote of thanks. He (Mr. Forrest) thought that the Association should possess a variety of apparatus, &c., for the use of the members, especially such things as all might be disposed to use occasionally, but which, by reason of their being too costly, individual members did not care to purchase for themselves.

After some discussion the council were requested to take the matter into consideration.

Mr. W. HARDING WARNER then exhibited and explained the method of using his ingenious camera tripod stand, with the additions for copying, &c. The stand was examined with much interest, Mr. Warner kindly giving all information respecting it, so that several of the members might have similar ones made for themselves. He (Mr. Warner) mentioned that in taking interiors there was often a difficulty in preventing the legs of the tripod from slipping on the polished marble pavement; but by inserting the points of the tripod in three common bungs, this danger was avoided.

Mr. O. R. GREEN presented to the Society's album a number of beautiful views which he had collected in America. Many of them had been taken by Mr. E. Wallace, jun., Secretary of the Philadelphia Photographic Society, and some by Mr. Jackson, Photographer to the U.S. Government Expedition to Colorado.

Mr. ATKINS exhibited a number of transparencies for the stereoscope, and an enlargement on opal glass, taken by the new "emulsion-without-washing" process, invented by Mr. W. B. Bolton. Each plate had been timed from instantaneous to six seconds' exposure, and the results gave evidence of the rapidity and excellence of the process. The transparencies were remarkably clean, and free from spots or pinholes. Mr. Atkins said he had seen Mr. Bolton prepare and dry twelve stereo. plates in seventeen minutes.

After some remarks in their favour by the president, a desire was expressed that some negatives should be obtained by the process, and exhibited at the next meeting.

Mr. O. R. GREEN'S prizes were awarded to Mr. A. Tyrer for the best six 12 x 10 dry-plate negatives, and to the Rev. J. D. Riley for the best twelve negatives, size 8 x 5 and under. All the negatives were taken by the collodio-bromide process. Mr. Keith and Mr. Warner acted as judges.

The PRESIDENT developed before the members two negatives by the gelatino-bromide process, and the meeting was shortly afterwards adjourned.

## Talk in the Studio.

**PRINTING IN COLOURS.**—Mr. F. J. Duck sends us the following method of printing in various coloured pigments:—"A piece of mica is spread upon the face of the negative, turned over the edge, and fastened at the back to keep it in its place. Then the various colours of the view, mixed with gelatine and bichromate, are spread upon the top of the mica in their proper places, and, when dry, exposed to light through the negative long enough to obtain a print; then developed with warm water."

## To Correspondents.

**W. ANDREWS.**—It is quite impossible to offer any opinion as to which is the best tent for out-door work. Much depends on the size of plates, much on the extent of the journeys, much on personal taste and habit. Almost every tent which has been devised has its advocates, and has been declared, by some of them, the best possible for some kind of work. We have given descriptions of many, from which our readers can select. Some photographers object to work with the head in the tent, and use a box with sleeves; others dislike the limited power of manipulation which sleeves permit, and do not object to work with the head in the tent or box. You will find an interesting article on the subject in our YEAR-BOOK for 1873, by Mr. Hudson, who has had considerable experience with different forms. 2. The box tent to which you refer is very excellent, and is used by many good men. Some, the best men, do first-class work in the simplest possible of tents, drapery supported by a central pole. 3. We gave all the particulars we received. A low lean-to roof with side light continued, the whole facing north, will give you a very simple and rapid studio.

**SOLOMON'S LAMP.**—Magnesium ribbon going out is generally due to some imperfection in the metal at that point. 2. Developed enlargements have generally a tendency to be grey and somewhat in the paper. Much depends on the quality of the paper. A hard English paper will generally give more brilliant images, and of warmer tone, than the French and German papers. Full exposure and rapid development are favourable to surface, vigour, and warmth of tone.

**VOTING PAPER.**—The balloting papers which will be sent out by the Secretary of the Photographic Society will not permit country members to vote unless they attend personally. It is to be hoped that in any new rules provisions of a more equitable arrangement will be made. Members only who have paid their subscriptions for the current year can legally be permitted to vote; but that does not, as you imagine, give any facilities to those who are several years in arrear to vote by paying one guinea for the present year, inasmuch as any payment they might tender could only be applied to the clearing off of arrears, a receipt for the current year only being given when all past arrears are paid.

**SUNDAY PHOTOGRAPHY.**—W. Colquhoun, of Alexandra, N.B., reminds us of his testimony some time ago to the fact that hard application to photography did not injure health. He now wishes to add that he scrupulously refrains from work on the first day of the week. No question can possibly arise as to the value of the seventh day's rest, and the majority of photographers doubtless scrupulously observe that rest; but, as we have before said, we cannot discuss the religious obligations of the Sabbath in these pages.

**TROUBLED.**—We have devoted several articles recently to the consideration of the minute yellow spots, some of the causes still eluding investigation. Those in the print you send seem to proceed from the paper.

**AN OLD SUBSCRIBER.**—You will find Albert's specification in our YEAR-BOOK just issued, and many articles on analogous processes in recent numbers of the NEWS and last year's volume. We have, during the last five years, published so many scores of articles on the subject, that it would be a serious task to indicate all the numbers, and many of them are now out of print. In the YEAR-BOOKS for 1870, 1871, and 1872 you will find articles. Crystallization is due to the use of excess of bichromate.

**KINWOOD.**—The simplest plan for your purpose, and one involving the least trouble, will consist in obtaining dry plates ready for use, which may be developed at leisure. You will find announcements in our advertising columns.

**KNOW-NOTHING.**—We cannot recommend special lenses or makers in this column. You will find information in our advertising columns. 2. The photograph you enclose can be registered. Send details, with eighteen stamps, to our publisher, who will get it registered for you. Each different position must be registered. You undoubtedly have a claim to the copyright, and no one can legally copy the picture; but any one else may, if opportunity serve, photograph the same thing.

**DAVIES.**—You will find full information as to where sheet gelatine may be obtained on page 139 of our last volume; the number is that for March 21st, 1873. Messrs. Sanson and Co., Thornhill Square, London, N., manufacture it.

**J. E. P.**—We never tried the use of benzoline in producing matt varnishes. It is not the same as benzole. The only mode in which you can ascertain will be by trying. You will find excellent instructions for making such varnish in our YEAR-BOOK for 1873, by Mr. Alfred Hughes.

**BENJAMIN.**—The proportion of water in a toning bath chiefly affects the rapidity of the toning. From five ounces to ten ounces to a grain of chloride of gold may be used. The proportion of lime water to be used is just as the formula describes: sufficient to neutralize any acid in the chloride of gold.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHING IN GOVERNMENT OFFICES—A STATUE FOR NICEPHORE NIEPCE—ENAMELS—THE ELECTIONS—GELATINE, ALBUMEN, AND COLLODION.

*Photography in Government Offices.*—It is gratifying to find that the Government of almost every civilized State has adopted photography in their printing offices, in some form or other, and this fully acknowledges the great services the art can render in the production of printed matter of all kinds. Even in the Colonial offices in Australia and Canada, photo-mechanical printing is largely resorted to, while in the Topographical Ordnance, and State Paper Offices of England, France, Austria, Russia, Belgium, Portugal and America, and, we think, also, in Prussia, the camera has an allotted task to fulfil. The reproduction of ancient MS. and autograph writings is an important branch; but the main use of mechanical photography, in most countries, seems to be the copying of maps, which are prepared from one and the same design on different scales. Topographical photography is, indeed, just now, very widely practised.

*A Statue for Nicéphore Niepce.*—Some years ago there was to be seen in the Museum of Chalons-sur-Saone a model of a monument to be erected in that town. It was a design for a full-length statue of Nicéphore Niepce, one of the inventors of photography, whom the townsmen of Chalons desired to honour by setting up a picture of him in his birthplace. But up to the present time we have heard no more of the promised structure, and it is to be feared that the question, if not altogether forgotten, has been, at any rate, overlooked. It is to be hoped such is not the case, for the erection of a memento of this kind would do very much towards bringing forward Niepce's name, and giving it the place of honour it should occupy in the memory of his countrymen, a position which for some years past has been placed in great jeopardy.

*Enamels.*—A question has lately been put, why are not photographic enamels more largely produced than is at present the case?—the beauty and permanence of such photographs are admitted on every hand, and the manner of producing them has now been openly published. This, of course, is true enough, but the production of pictures on enamel is, unfortunately, not so easy of accomplishment as other photographic printing. An acquaintance with the process is but very little towards it, for the work not only requires delicate and practised manipulation, but when success is achieved in this respect, there remains the critical and very risky operation of burning in the result. Indeed, until the picture is perfectly finished, one cannot be at all sure of the result of one's labours, whether success or failure will crown one's efforts. This uncertainty seems, indeed, inherent to the process, in a great degree, and for this reason photographic enamels can never become very common, a circumstance which, to many, is a subject for congratulation.

*The Elections.*—It may be interesting to know that among the successful candidates there are two gentlemen who are well known as accomplished photographers. At Wigan, Lord Lindsay succeeded in attaining a position at the head of the poll, having come forward but a short time previously to the election as a supporter of Mr. Disraeli; while in Herefordshire, we find Major Peplow returned, who is also an advocate on Conservative principles. Both these gentlemen are well known in the photographic world, Lord Lindsay as a clever astronomical photographer, who is to take a leading part in conducting the operations for the observation of Venus, and whose fine pictures of the last solar eclipse will still be fresh in the remembrance of all. Science has, indeed, gained an energetic supporter in the House of Commons by the

election of Lord Lindsay. Major Peplow, again, has been some time past a regular exhibitor at the annual exhibitions of the Photographic Society, where he has distinguished himself as a very capable landscape photographer.

*Gelatine, Albumen, and Collodion.*—It is very singular how, in photographic manipulations, the changes are continually being rung upon these three substances, and scarcely any other. Whether it is a question of producing clichés in the camera, or producing prints from negatives, one of these three substances is sure to be chosen as a vehicle for the photographic image. Other substances have been tried in turn, such as silk dissolved in hydrochloric acid, gums of a special nature, bitumens, and such like, but these have had but comparatively little application. Collodion, albumen, and gelatine, are used indiscriminately in the production of negatives for carrying the sensitive salts; and although the last-named has, till now, been used but very little, still there seems a prospect of gelatino-bromide plates becoming popular, if the claims put forward for gelatine emulsions are shown to be well-founded. It is the same in the printing processes, but, in this case, the gelatine, which is used least for the preparation of negatives, is employed most frequently, and collodion, again, which is the main support of negative work, is rarely employed for printing. For not only does gelatine enter into the constitution of carbon prints, but is an important element in every mechanical printing process one can think of: in Woodburytype, Lichtdruck, Heliotype, Photo-lithography, as well as metallic engraving methods, where it is employed for covering up the reserves while the rest of the plate is etched with acid. In modern processes, indeed, which are fast attaining a permanent footing, gelatine is universally employed together with the bichromates, which are thus every day usurping the place of silver. Everybody knows, too, how extensively albumen is employed in the silver printing process, and paper spread with collodion also receives some employment. But we seldom employ any other vehicle except in plain paper printing, where arrowroot, algin, and shellac are occasionally resorted to. One seems to have discovered in the early days of photography how very suitable these substances were for photographic manipulation, and since that time all the efforts made by experimenters have not been successful in discovering a fourth body possessed of qualifications in any way equal to the three first suggested.

### AMERICAN CORRESPONDENCE.

WHAT THE PAPERS SAY—SULPHATE OF SILVER PINHOLES.

*What the Papers Say.*—I notice, especially when you are holding your annual exhibitions, that you are very susceptible to what the papers say about you; and I confess we are too, for, as much as it helps along in the arts and the sciences, photography seldom gets award of real genuine praise from the newspapers, and for that reason, when it does, I feel that we should acknowledge it, so I add a few extracts from an editorial which recently appeared in Mr. Geo. W. Child's paper, the *Public Ledger* of this city. It is headed "Good for the Photographers," and says:—

"The *Philadelphia Photographer*, which has just completed the tenth year of its existence (growing with the growth of the art it illustrates), has given some advice to photographers that should be echoed through all trades and professions. It says: 'What shall I get up for the Centennial? is a query which every photographer should ask himself now day by day, and prepare for a substantial answer. The Centennial Exhibition is not to be an ordinary one, such as we have each year under the auspices of the National Photographic Association, but a very extraordinary one, where your best work should be shown in elegant style. The Centennial Commission are disposed to treat photographers very favourably, and to have a hall especially constructed for the art

of photography. This being the case, let us not fail to do our best, including liberal subscriptions to the stock.'

"Few departments of the exhibition can be made of greater public interest than that devoted to specimens of photography. As an art, it is much younger even than the youthful nation among whose industries its best results will be exhibited; and, although it now takes rank with those arts that are older than the nation, it has before it a future to which its present position is hut a step. The public obtains some notion of the advances made in photography by the gradual improvement in the pictures produced by this process, but does not realize that the process itself has been almost revolutionized within the last ten years, and that to-day equally good pictures are made by modes of procedure based on two opposing principles. In some of its features photography is yet a mystery to those who practise it with the best effects, but the mystery is gradually being solved under well disciplined agencies, such as societies, annual conventions and exhibitions, and monthly magazines entirely devoted to the discussion of problems of photography in its relation to art, optics, and chemistry. Probably the best agency is the National Association, which holds annual conventions, where papers are read and discussed, and the pictures made by different processes are exhibited. At the last convention of this Association, discussions were held, which curiously illustrated the fact that the 'scieuc' involved in photography is no more exact than some of its more pretentious sisters. One set of photographers, it appears, used a bath for negative plates, containing a large proportion of acid and a small proportion of silver, and another set used a bath strong in silver, but only slightly acid. Each set produced good pictures, while the conservatives could see no advantage in using either formula of the radicals, as they by a medium course also produced good pictures. There was a similar disagreement on the subject of skylights and on many other questions involved in the art. All of these disputed points must be settled before photography can make a near approach to perfection, and the fact that they remain disputed, while such splendid specimens of the art are made as we daily see in shop windows, suggests the hope that in some period of the future 'the sun artist' will give us pictures as much superior to those of to-day, as they in turn are to the prints with which the town was satisfied ten years ago. Such results are ordinarily the slow outgrowth of patient study and experiment on the part of a few, but in photography, through the medium of societies, magazines, and exhibitions, the humblest member of the craft contributes something to the general fund of information, and aids in new discoveries.

"The work of the photographic chemist does not consist alone in the production of pictures artistically true in tone through the medium of chemicals, for photography has become of late the handmaid of the higher sciences, and the results of nearly every discovery in photographic chemistry have been utilized in some practical way for the benefit of mankind. Photography has a still greater value as a cultivator of art tastes, for it puts in the hands of the poorer classes exact representations of beautiful scenery, or exact copies of fine works of art, instead of the vulgar prints and coarse dabs that were common twenty years ago. Such an art is deserving of recognition in the exhibition of a nation where it has obtained, possibly, its greatest development.

*Sulphate of Silver Pinholes.*—Sulphate of silver, as we all know, is one of the most aggravating causes of pinholes. Mr. John M. Blake, whose paper on the use of bichromate I sent you a short time ago, has also been writing on this subject, and I send you what he says, hoping it will help many a one out of trouble:—

"Crystals of sulphate of silver often form during development when working with a strong bath (say sixty grains) and developing with sulphate of iron. The film may come out of the bath in perfect condition; but if we develop the plate, and then drain and blow upon the surface to remove still more of the solution, it will be seen that the film has a velvety look. This is caused by a multitude of small crystals of sulphate of silver. They will be removed by solution in less than a minute, if the plate is washed with water. For this reason they are quite likely to escape notice. The effect produced by the formation of these crystals is to cover up a portion of the film under each of them, and thus hinder the deposit. Pinholes are left on the solution of the crystals, and the general effect is to give a peculiar, coarse look to the image. Pinholes of this kind have not the character of a distinct puncture entirely through the film, since the growth

of the crystals, in the high lights at least, began after development had commenced. As proof that these crystals are sulphate of silver, it may be mentioned that their solubility in water is identical with that salt. Also a simple saturated solution of sulphate of silver does not act upon them. They form, as well, on a plain collodion film that has been soaked in the strong silver bath. If, while working a bath with which ordinary sulphate of iron developer constantly and abundantly gives these crystals, we substitute proto-nitrate of iron, or pyrogallic developer, the crystals cease to form; but simple sulphate of potash or of ammonia will produce them fully as well as sulphate of iron.

"The crystals by sulphate of potash are larger in size than those produced when sulphate of iron is used, and their microscopic character is also somewhat different. Those produced by sulphate of ammonia also have a character peculiar to themselves. Certain sulphates appear to produce these crystals out of proportion to the amount of sulphuric acid which they contain. Probably this is not due to the formation of a double sulphate of silver, since a crystal started with sulphate of iron solution was seen under the microscope to continue its growth in mixed solutions of sulphate of potash and nitrate of silver. In explanation, double salts are often less soluble than their two constituents, and a crystal of simple sulphate of silver would not be built upon by a double salt. If the crystal by sulphate of iron was a double salt to begin with—and this is possible—then super-crystallization might occur, and a greater difference in the facility of production of pinhole crystals by different sulphates than actually exists would be quite consistent.

"We will now add the results of some trials with several sulphates that are frequently added to the sulphate of iron developer. It must be understood that the results will vary within certain limits, according to the habit in flowing the developer, and the consequent amount of dilution or loss of silver nitrate; also upon the amount of exposure, and consequent absorption of silver in forming the image. The examples given were at the maximum; plain collodion films were used, soaked in the different baths; temperature, 60° to 70° F.

"A solution of sulphate of iron, 100 grains to the ounce, gave no sulphate of silver crystals on development with a film taken from a 40-grain silver bath; on one from a 45-grain bath a few crystals formed in the thick edge of the film; a 55-grain bath gave them abundantly; a 50-grain iron solution behaved the same as the 100-grain; a 25-grain iron gave none with a 45-grain bath, a very few with a 50-grain, but abundantly with a 60-grain bath; a 15-grain iron solution gave none with a 60-grain, a few with a 65-grain, and more with a 72-grain bath.

"A sulphate of potash solution, 30 grains to the ounce, gave a few crystals with a 40-grain silver bath, and a 20-grain potash also a few with the same bath; a 13-grain potash gave none with a 55-grain silver, but a few with a 60-grain bath; a 9-grain potash gave a few with a 66-grain silver.

"A 20-grain sulphate of ammonia solution gave the crystals with a 40-grain silver; a 13-grain ammonia gave a few with a 45-grain silver, and abundantly with a 60-grain silver; a 9-grain ammonia gave a few with a 55-grain silver.

"A 40-grain sulphate of copper gave a few crystals with a 40-grain silver, and abundantly with a 60-grain; a 20-grain copper gave a few with a 50-grain, and abundantly with a 60-grain silver; a 13-grain copper gave none with a 60-grain, but gave them with a 66-grain silver.

"A 40-grain double sulphate of iron and ammonia gave a few crystals on the thick part of the film with a 45-grain silver, and plenty with a 50-grain; a 20-grain double sulphate solution gave none with a 55-grain bath, but abundantly with a 60-grain.

"An appreciable interval elapses after the mixing of the solutions on the plate before the crystals begin to form, and if the development of an image commences and goes on vigorously during the interval, the trouble may not appear. Furthermore, it will be seen from the results of experiments given above, that if we confine ourselves to the strength of solutions that general experience has shown to give the best and most uniform results with bromo-iodized collodion, there will be no danger of the formation of these pinholes; also that a limit is put to the strength of solutions we may wish to employ for the purpose of forcing up an image with a very short exposure, excepting what might be gained by heating the developer to increase the solubility of the sulphate of silver."

(To be continued.)

TRANSPARENT POSITIVES FOR ENLARGEMENT.

THE following method of producing a transparent positive from which to obtain an enlarged negative gives singularly fine results. We extract it from the useful little manual just issued by Mr. Solomon, "Photography in Four Lessons."

"Assuming that a good small negative has been obtained (one which is sharp, delicate, and full of half-tone), the most important aid in securing a fine enlarged negative from it consists in a method of producing a good and suitable transparent positive from it. A good transparent positive for this purpose differs in some essential respects from a good transparency for the stereoscope or magic lantern. Of the latter it is a good test that it shall look well as a picture when laid down on a piece of white paper, being very clear in the lights, and not over-loaded with deposit in the shadows. A first condition in the transparency for enlargement, after good definition, is, it should not be suitable for examination in the way described: its chief characteristic should be the possession of full detail and sufficient deposit in every part, without a trace of bare glass except in some minute points of extreme high light. Whilst it is important that the transparency should be covered with well made out detail, it is equally important that the deposit should be of the most delicate character, as free from texture and granulation as possible. The image of an ordinary collodion transparency developed with iron may, for instance, appear to the eye delicate and fine, but it will be found, when magnified in enlargement, to be coarse and unsatisfactory, the texture of the film and that of the deposit of silver as reduced by the iron developer presenting a rough, granular appearance, which will be very offensive in the print from the enlarged negative. This subject has received considerable attention of late, and the necessities of the case are much better understood by photographers than formerly; but how best to meet them still remains a question, the best methods having been kept secret. The formula we are about to lay before the reader has not been published before, and is one of the best in existence. The image, being obtained on the textureless film presented by albumen, is free from the objections which a simple collodion film presents, and the homogeneous character of the deposit of silver produced by pyrogallic acid development prevents anything like granulation, whilst its non-actinic colour gives it especial value in securing sufficient vigour without over-intensification. By means of the following formula a transparency may be produced giving the utmost delicacy, modelling, and brilliancy, in the enlarged negative. The process, as will be seen, is a modification of the collodio-albumen process, and the plates are intended for contact printing. Take—

Albumen ... ..	12 ounces
beat well, and allow to stand a few hours. Then add:	
Water ... ..	2 drachms
Acetic acid ... ..	48 minims
Shake well, and filter. Then add:—	
Water ... ..	12 drachms
Iodide of ammonia ... ..	72 grains
Bromide of ammonia ... ..	12 grains
Ammonia forte ... ..	1 drachm

Take a powdery iodized collodion, and pour on a well-cleaned piece of plate glass in the usual way, after which put it into water until all greasiness disappears, and wash well under the tap. Now pour on a small quantity of albumen to flow away the surface water on the collodion, and throw it away; then flow from the thumb and opposite side, fresh albumen, repeating this two or three times, taking care not to return the albumen in a wave back on the plate, or it will give a mark. When the albumen has flowed over the plate as described, put it up to dry, and

when dry sensitize, rinse, dry, and pack away for use when wanted.

	<i>Sensitizer.</i>			
Water ... ..	...	...	...	12 ounces
Silver ... ..	...	...	...	1 ounce
Acetic acid ... ..	...	...	...	1 "

Sensitize in ordinary temperature one minute, or hot weather forty seconds. When the plate is taken from the silver bath, slightly wash or rinse with distilled water, and put it on end or in one corner to dry. Expose under the negative for a few seconds to good daylight. Experience will be the best guide as to time of exposure, which will vary with the condition of the light and the opacity of the negative.

"To develop take—

Pyro ... ..	15 grains
Acetic acid... ..	2 drachms
Water ... ..	8 ounces

In winter warm the developer.

If the exposure has been sufficient, a well modelled transparency covered with detail, but not overloaded with deposit, will be secured. Fix with—

Hypo ... ..	6 ounces
Water ... ..	28 "

"The transparency may, after washing and drying, be used in its present state, or its brilliancy may be increased by toning as follows:—Dissolve 15 grains gold in 2 ounces of water, and pour gradually the gold into the hypo, shaking it or stirring it whilst pouring in the gold.

"To keep the hypo and gold fixing and toning bath clear and properly neutral, put in a nut of hard chalk. In winter, warm the pyrogallic solution. If a bromo-iodized collodion be used as a substratum, a backing will be necessary to prevent halation. Burnt sienna finely ground in gum-water will answer this purpose."

GERMAN CORRESPONDENCE.

BY DR. VOEL.

MICRO-PHOTOGRAPHIC STEREO SLIDES—THE ABSORPTION OF ACTINIC RAYS IN THE ATMOSPHERE—EFFECT OF LENSES OF STRONG OR FEEBLE LIGHT ON THE BRILLIANCY OF THE PICTURE—DULL WEATHER IN GERMANY.

THE attention of the public has recently been directed to a special kind of stereoscopic pictures, but, so far, only a few of them have been published. I refer to stereoscopic views of microscopic objects. Micro-photographs are plentiful, and as magic-lantern slides they form an article of trade; but stereoscopic pictures of microscopic objects are much more instructive, for from them we learn what is near and what is far, what is hollow and what is elevated. Such stereoscopic effects are furnished by the binocular microscope, an invention of your countryman, Biddle (1853), for the naked eye. But, so far, binocular microscopes are very expensive, and only in the hands of a few. It is easy, however, to make these stereoscopic pictures with any ordinary microscope. It is done by skilfully blending the object lens of the microscope. Years ago I called attention to the fact that a very large lens—for instance, a portrait lens—yielded a picture quite different from the one taken with a lens of smaller opening. The right half of the lens takes in more of the right side of the person, and the left half of the lens more of the left side of the person. If we now cover one-half of the lens, and take two pictures, one with the right half and the other with the left half, the two together will give a stereoscopic effect. We can employ the same principle to make microscopic pictures. The lenses of the microscope are, of course, very small, but still they are much larger than the object, which is a mere speck; in fact, they are, when compared with the object, still too large. If we stop off, first the one half and next the other half of the lens, and

take a picture, we obtain a very complete stereoscopic effect; and Dr. Frith has made, in this manner, excellent micro-photographs for the stereoscope.

Lately I have made a number of spectral observations, which have furnished me important data on the changes of the chemical light intensity in the atmosphere. It has been known for some time that the chemical intensity of the light of the sun becomes more feeble in proportion as the sun approaches the horizon, and that watery vapours decrease the chemical intensity. There are, however, other circumstances which affect the transparency of the atmosphere. I noticed this when making my experiments with bromide of silver plates. Sometimes, with a perfectly clear sky, I obtained only a very limited picture of the spectrum; and at other times, when the atmosphere was less clear, the picture was much more complete. For instance, on October 7th, at 2 o'clock p.m., I obtained, with ten minutes' exposure, a picture extending from violet to red, while on October 17th the action extended only to near the yellow, while at the same time the sensitiveness to ultra-violet was greater. On the 18th of October violet had no effect at all on the bromide of silver, while red acted considerably. On October 29th the action of violet was still more feeble, while that of red increased. One day later, the photographic action of the violet had increased again, red having decreased correspondingly. In short, you see how fluctuation in the intensity of the chemically active rays occurs, of which the eye perceives nothing; and it is only to be regretted that we do not possess a reliable instrument—a photometer—with which we can measure these vibrations. The chemical photometers which have been constructed so far determine only the combined effect of the solar light, but make no distinction in the action of the different colours, which, as my experiments have demonstrated, is very variable. So far, the violet, the blue, and the green rays—or, in other words, the rays of certain colours—have proved photographically practicable; a photometer should therefore fix the light intensity of these colours, in order to become practically useful.

In your August number, page 227, I wrote to you concerning the action of objectives, either feeble or strong in light. The belief is very widespread that the former, even with a correspondingly longer time of exposure, do not yield as brilliant pictures as the latter. I found that this belief was erroneous, and the reason of it is that with long exposure a considerable portion of the silver solution drips from the plate, and hence the developed picture appears weaker than a plate which is developed after a short exposure, and where the larger portion of the silver bath adheres to the plate, and hence, on being developed, yields a more brilliant picture. According to my opinion it is not the objective of great light intensity which yields the brilliant picture. Our friend Simpson has his doubts about this view. He maintains that the greater brilliancy of pictures taken with light, strong lenses has been established on dry plates, on which a dripping of the silver solution is out of the question. I admit that my friend Simpson is right in this particular (*i. e.*, that light, strong objectives yield more brilliant pictures with dry plates than objectives feeble in light), but I dispute the conclusion drawn from this, namely, that the light intensity of the instrument is the direct cause. So far as I know, nobody has made comparative experiments (*i. e.*, worked with two instruments simultaneously), and fixed the time of exposure reverse to the light intensity of the instrument. Experiments with instruments the light intensity of which is exactly known can only decide this question. The experience that objectives feeble in light yield weaker pictures on dry plates, I explain quite differently. Experienced dry-plate workers know very well that it is better to take the time of exposure a little too long than too short. This rule they employ principally with weak objectives. They expose, fearing under-exposure, rather too long than too short,

and the results are feeble pictures. The cause is, therefore, an individual one, and the instrument is not to blame, but rather the worker, who, generally, does not know the exact light intensity of his objective. That this is actually the case I have recently established practically. I took three tannin plates, and exposed them in a stereoscopic camera, the opening of one of the objectives being stopped off in such a manner that its light intensity was twelve times less than the other, and I exposed the plate under the "stopped off" lens twelve times longer. The result was that the two negatives developed with equal rapidity, and the brilliancy of the two pictures was absolutely equal. I cannot, therefore, change my former opinion, and insist upon what I have said before.

Everyone here is complaining about the weather; for two weeks we have not seen the sun. The precious Christmas days, which generally bring numberless orders, have passed by without bringing any business. Some photographers have taken medallion cartes by lamplight with tolerably good results.—*Philadelphia Photographer.*

#### —♦— PRACTICAL HINTS BY A LANDSCAPE PHOTOGRAPHER.

THE old story: "I really have no secrets." This is the preliminary remark of Mr. Frank Good (whose charming landscapes everybody knows) in communicating a few practical hints to Mr. Badeau for *Anthony's Bulletin*. We proceed to give a few of those hints, which our readers will find worth noting, although they are not secrets. He begins by giving two or three bits of axiomatic advice as follows:—

"Never study economy in lenses, apparatus, &c.

"Never attempt any subject if the light be not suitable. As, however good the picture (or rather I should say negative) may appear, it always disappoints one afterwards.

"Never focus carelessly. Very much depends on this. As a rule it is a good plan to focus some central object in the view. (*N.B.* All these observations are for landscape photography.) For interiors especially this is a most important matter, and sometimes difficult. It is a good dodge to fasten up some large type—the heading of a newspaper, for instance—in a central position. This gives one a good chance of getting a sharp picture.

"Never use any but the best patent plate, which, by-the-by, do not clean with anything but alcohol, as tripoli, &c., only adds another evil to the bath.

"Never waste time in doctoring an old bath. Make a new one, and this as simply as possible, thirty-five grains of silver to each ounce of water; add a little old collodion, filter, and it is ready for immediate use. (I have always found that the ordinary nitrate of silver answers every purpose.)

"Never, after securing one good negative, leave the ground till you have tried for a duplicate, which is often better.

"The greatest secret in the negative process, to my mind, is a properly-timed exposure; herein lies the great art of photography, and makes the difference between a picture and a photograph. If you are required to drag out your child, he only looks sullen when he appears.

"Now, perhaps many of your readers may exclaim, There is nothing new in all this: nor is there. And some may say, That is just what I do. To these I say, keep on doing so, and success must follow. Now for a few words on printing, and I shall have had my say.

"Many photographers seem to think when a good negative is turned out that it must of necessity give good prints. To my thinking this does not follow, for the same care that was required for its production is still necessary to produce the best results on paper; and a photographer who does not occasionally print can scarcely expect or be expected to get all the qualities in a negative for a choice printer. I give as much attention to this branch as to

negatives, and consider it a cruel thing to leave such nice work to the care of boys and girls."

Having enforced "these few precepts," he proceeds to the subject of printing, which he regards as all-important. He says:—

"Good paper is essential. The Saxe is our favourite. This with a thirty-grain bath gives brilliant prints. The sensitizing should be done in a warm room, and after the usual floating time (three and a-half minutes) hang up to drain. Before another sheet is added, add two drachms of a solution of nitrate of silver (strength one drachm to the ounce). This supplies the waste; and, after the addition, stir well by passing a plate of glass backwards and forwards. This being done carefully produces no bubbles, and gives each sheet of paper fair play, the last dipped being equal to the first. Dry off before the fire, and stow away in a large blotting book made for the purpose. This flattens and dries up all damp corners, and keeps the paper in excellent condition for printing. Prints upon paper prepared carefully lose little in toning. Before doing this, wash carefully by passing through three changes of water (soft water, if procurable) singly; and lastly, before toning, sponge each print. This removes any surface chloride, makes them tone readily, and keeps the bath in good order. For general work no bath that I have tried works so well as the old soda bath prepared as follows:—To each grain of solution of chloride of gold add ten grains of carbonate of soda (of course adding the gold to the soda), which is first dissolved in a little water. Shake well at intervals during twenty minutes to half an hour, and add sufficient water to make up enough for the toning bath. Half a grain of chloride of gold tones one whole sheet of paper.

"This bath in winter can be used for a week or more by adding more gold prepared as above. I may mention here that the silver bath, if hardly worked, should be boiled down nearly to dryness once a week, and a pint or so of fresh solution added according to quantity, together with a little carbonate of soda to correct acidity. Prints toned as I have stated lose scarcely anything in the hypo solution. This should always be fresh and strong, the prints being placed in one at a time; when all are in they should be constantly turned, and after they have remained half an hour, drain out the hypo, and pass one by one into a large vessel of water. After one or two changes, to get rid of as much hypo as possible, proceed to roll on a glass slab with a heavy iron cylinder covered with flexible india-rubber. This squeezes or wrings them, which does more good than hours, or even days, of soaking. Wash still in more changes of water, warm and cold, roll again, and hang up to dry upon rods of wood made for the purpose, varnished with shellac varnish; lastly, iron them, when dry, one upon the other, which is the quickest manner of flattening them.

"I fancy prints so prepared are permanent. All this reads troublesome, but in practice it will, I think, become quite as easy as any other method. Never send out a bad print. Consider each print as an advertisement of your beautiful art. Endeavour to make each picture perfect."

### COMBINATION PICTURES.

BY J. M. YOUNG.

OF course all pictures are, or ought to be, combination pictures. Art rules should be followed in every photograph with the object of making it a picture; but what I am to say a few words about are pictures printed from more than one negative. This class of photograph has been objected to by some of our art critics as beyond the province of photography—degrading to its truthful character. Yet I believe, if well understood, the art of combination in photography is a legitimate power in the hands of the photographer; and with this view I submit the following method of working, which will be found a source

of very great pleasure, and by no means a despicable source of profit to those who may give it a thorough trial. Let me say, however, that I do not pretend to teach anything new. I merely give what I have picked up and pieced together into a system satisfactory enough to myself.

*The First Negative.*—This contains the foreground, which should be made up of natural objects (*papier mache*, as painted stumps, rocks, &c., will not do). Do not crowd too much into the picture—merely sufficient to give or support a character to your figure. (2) The figure. As to this I can only say, let it harmonize with the character you wish it to represent. If rustic, a pair of elastic side boots or a magnificent chignon had better be left in the dressing-room.

*The Second Negative* should contain the middle distance, foliage, mountains, or other scene suitable to the figure. Be careful as to point of view, composition of lines, lighting, &c.

*The Third Negative.*—The sky. Any fine clouds effects should be secured when the opportunity occurs. The same caution as to the lighting applies to the printing of the sky.

*The Combination.*—The first negative, with figure and foreground, may be taken against a grey or slate screen graduated towards the top to nearly white. In my practice I prefer having the screen quite plain—*i. e.*, without any gradation—and of a darkish slate colour from top to bottom, the gradation being easily got in printing by judicious masking. A great many different effects may be got in this way, such as mist rising from a valley, snow on the mountain sides, &c., &c., to suit the subject or vary the picture, and the practice of this will greatly add to the pleasure of the work. Having chosen the suitable negative for your background, draw the outline of your figure and foreground roughly in any opaque ink, or colour, on the glass side of the landscape negative, and proceed to block out the whole of the objects which might print on to the figure or foreground. When this is done place the print of your figure and foreground in contact with the background negative, seeing that the figure, &c., is properly protected by the rough mask, and print in direct light, not too deeply. All that now remains to be done is to print the sky, to have this, your first effort, complete. Select your cloud negative, and place in contact with your doubly printed proof, protecting figure and background with a rough, movable mask, such as a piece of brown paper torn to something like the outline of your mountains, or other subject forming the background, and print as before.

I only add, beware of spottiness in your composition. Have all in a subdued tone rather than so obtrusive as to quarrel with your subject, the figure, for the greater prominence.—*Photographic Bulletin.*

SAVING SPILT SILVER SOLUTION.—A correspondent of our Philadelphia contemporary describes an accident in the operating room, and the mode of dealing with it. He says:—"Just before Christmas, in making up a silver bath the bottom of the bottle came off, by a hard knock, and the silver (two pounds) went on to the dark-room floor. There was pretty lively work for a few minutes mopping it up with towels and any old clothes we could get hold of, and wringing out into an evaporating dish. It was a sorry-looking mess, being a mixture of silver, hypo, iron, and dirt. The young man working for me suggested throwing it down with strips of copper, obtained at the coppersmith's. This was put into the bath and allowed to remain some hours, or until by adding muriatic acid there was no precipitation to the water. Again, this was now washed thoroughly in a good many changes of water, until by adding weakened ammonia there was no longer observed a change to the blue tint. Then, being well drained and put over a heater where there was a chimney to carry off the fumes, a mixture of nitric acid one part to two of water was poured on in sufficient quantity to dissolve the silver. Evaporated and fused, it made as good a bath as 'never was.' Not more than half a pound of silver was lost."

## DISRUPTION IN THE PHOTOGRAPHIC SOCIETY.

ON Tuesday evening last, through the vote of a special meeting, the Photographic Society of London lost, at one swoop, the whole of its officers. In a society numbering between three and four hundred members, of whom more than two-thirds reside in the country, the vote of twenty-eight town members in a meeting consisting of little over fifty persons—or, to put the naked truth more barely, a majority of six persons—deprived the society of president, vice-presidents, council, treasurer, and secretary, the whole of the twenty-four offices being, for the time, left vacant. The cabal has succeeded: and we wish its promoters joy of their victory. They are, after all, little to be congratulated on an issue which, probably, transcends their ambition, and lays on them a heavy responsibility, a responsibility which, we earnestly hope, for the society's sake, they may be able to sustain without dishonour to themselves, and without loss to the members and to the art which the society has so worthily fostered and represented.

The main facts of the story are briefly told, and may be found more in detail on another page. The special meeting was held, and, unhappily, very sparsely attended. Members generally are not deeply interested in squabbles, and, as we have before said, are apathetic about laws. At any rate, there were insufficient independent members present to affect the voting. The amendment of the council offering harmonious co-operation in reforms was rejected, and in such terms as left the council no alternative, consistent with self-respect, but resigning in a body.

Mr. Hughes proposed the resolutions of the requisitionists in an aggressive speech, devoted less to an exposition of the necessity of a change in the laws than to an impeachment of the council, whom he charged with acting illegally and disrespectfully to the signers of the first requisition. The utter groundlessness of such a charge was clearly and temperately exposed by Mr. White, who, as an experienced lawyer himself, pointed out that the council had no power to act upon a requisition not in accordance with the laws, but showed their readiness to carry out the purposes indicated by offering to co-operate with the signatories in a modification of the laws. It is pretended now that this was regarded as an attempt to shunt the reform. But a fact remains which no railing can remove. Four of the gentlemen styled requisitionists were present when this tender of co-operation with those desirous of reform was agreed on in the council. One of them seconded the motion. All of them voted for it: it was carried in the council without a dissentient vote. Now, the allegation is that these gentlemen reported that the council were obstructive and opposed to reform. We emphatically deny that this was so; and we point to the unanimous

resolution in which these gentlemen joined, as effectually confirming our statement. One of these gentlemen asked of how many the deputation should consist, and the answer was, "as many as the requisitionists chose to appoint—all, if it so pleased them." And this offer of co-operation, and this invitation to meet, is now pronounced to be lack of consideration and respect! This was one of the alleged reasons for declining to accept an amendment from the council.

Another objection was that the proposed committee had no instructions. The truth is that an instruction, as definite as by any possibility could be framed, short of tying the hands of the committee, was given in the preamble to the amendment, which states that the laws can, with advantage, be placed upon a wider basis, that the choice of officers can be more completely placed in the hands of members, and better facility afforded for frequent distribution of offices amongst the members. But this was not sufficient. Any committee appointed was to be hand-tied at the outset, and pledged to maintain certain principles embodied in the two rules which a *junto* had decided, *bongré mal gré*, to force upon the society, a primary principle of these rules being the complete ignoring of upwards of two hundred members of the society non-resident in London. A faint attempt was made to explain that steps might be taken afterwards to give votes to country members. But this is absolutely negated by the resolutions which it was insisted must form the test principles upon which a committee must work. In the new Law VII. it is distinctly laid down that nomination can only be made by members *present*, and no country member can now take part in the nomination of officers until the rule passed on Tuesday night, and emphatically insisted on for the guidance of any revising committee, be rescinded. At this moment country members have less voice than ever in the affairs of the society of which they form a major part. And unless the committee appointed by the requisitionists are impelled, by the close logic of their opponents, to make some provision for representing country members, in spite of the instruction obstructive to which they are intended to conform, the mass of the society must be left out in the cold, without an interest of any kind to connect them with the body which depends on their support for existence.

Another objection to the council's amendment was, that it suggested that out of nine members, three were to be nominated by the council, six being left in the power of the requisitionists. Mr. Hughes objected to the council wishing to nominate any of the committee, and, with exquisite taste, asked who were the "three dark horses." Leaving at once this flavour of the stable or the turf, we might ask if there was anything unreasonable in supposing that a council of gentlemen, who have for some time been engaged in managing the affairs of the society amid very serious difficulties, should have some special fitness for suggesting three of the most suitable men to assist in revising the rules? These three could only advise, and could in every point be out-voted by the six representing the requisitionists. How far the statement that it was the sole right of the members of the society to nominate a committee was really made in good faith, may be gleaned from the fact that when the requisitionists subsequently appointed a committee, the mover of the resolution suggested that the entire nomination of the members thereof should be left in the hands of Mr. Hughes! This was too serious a violation of appearances, and was over-ruled.

The fourth objection to the amendment was a singularly ingenious one, and to it the requisitionists owe their victory, for we have been informed since, by several who voted with them, that had they not been misled in this matter, they would have voted for the council's amendment. The statement had been circulated that the sentence which directed the committee to be appointed to report to a general meeting, meant an *annual* general meeting, and

that the amendment was simply a subterfuge to put the question aside for twelve months! By what perversion of common sense such a conclusion was arrived at by honest workers in the movement we are at a loss to conceive. In all cases of the kind, when a special meeting is called for a special purpose, it is adjourned from time to time until that purpose is accomplished; and had a committee been appointed, the special meeting of Tuesday night would have been adjourned until a specific time appointed by that meeting to receive the report of the committee it had appointed. There was no other course open, and the council had no other idea. The notion of delaying for twelve months never was, for a moment dreamed of; but if it had been, as the committee was to consist of such an overwhelming majority of the requisitionists, they had the matter in their own hands, and could have decided to report at any time they chose.

But the question was never intended for consideration at the special meeting. It was all cut and dried beforehand by the requisitionists. We have before us the private programme of a meeting held a few days beforehand, deciding how the matter was to be worked. This private programme, printed for the guidance of the opposition, was handed to us by a gentleman who had been deceived by the statement that the amendment meant delay. The arrangement is as cunningly devised as it was successful. The instructions are precise. First, "That the new laws be voted for;" second, "That the amendment be rejected;" third, "That Mr. Hughes's motion for a committee to revise laws be voted for;" fourth, "To vote for the following candidates," giving the names, which will be found in the report of the meeting. A list of names with persons appointed to move and second them, for serving on Mr. Hughes's committee, follow. The programme concludes by earnestly requesting that, to ensure success, all holding it "will vote according to this programme." They were not to go to the meeting to hear the case stated, to listen to explanations, and vote honestly upon the case placed before them; but they were pledged to vote against the council in any circumstances. Thus it will be seen that the proceedings of Tuesday night, the voting on resolutions, and the election of officers by ballot (!) was not the work of the Photographic Society, but the predetermined work of a junto, secret, self-appointed, and irresponsible. It is clear that when proceedings of such a kind are resorted to, any *emete* may succeed, as the council could only proceed by direct open reliance on the direct and open conduct of the members.

The resignation of the council after the expressed and implied want of confidence was simply inevitable, although it evidently took the meeting by surprise. The only requisital which a society can offer a body of officers for the honorary discharge of duties which levy a heavy tax upon them consists in loyal confidence. That confidence withdrawn, men of any self-respect at once tender their offices to the society. The step was inevitable; but we cannot the less regret that the society has suffered a great loss. In the president they have lost a gentleman whom they will not readily replace, either in position, scientific repute, or capacity for the office. Some members of the council they will not easily replace. Among the requisitionists there are some gentlemen of high character, sterling honesty, and great ability. How their judgments have been warped to the approval of a course which seems to be so unfair, so impolitic, and so menacing to the welfare of the society, we will not venture to conjecture. They have now a heavy responsibility, which, as we have said, we devoutly hope they will use wisely, so as to avoid, if possible, the destruction of the society. Brief as is the time which has elapsed, we have heard much talk of resignations. On this point we earnestly conjure members not to act rashly. The society is more important than any set of officers. Its influence has been valuable—may yet be valuable. The future is not as promising as it might

be; but if the members generally are loyal, no permanent injury can arise from a temporary disturbance. The narrow and exclusive rules passed on Tuesday evening have not yet become law, and may not do so. The presence of half-a-dozen more loyal members—the presence of all the members of the council even (for some were unavoidably absent)—would have changed the issue of the evening; and the members of the society generally can at any time, by a little earnest attention to the matter, prevent it falling into the hands of any clique, junto, or cabal. It is surely better to exercise their legitimate power and influence than to leave a society with a noble history and traditions to drift to destruction.

#### MR. CRAWSHAY'S PRIZES.

WE are authorized by Mr. Crawshay to announce that in deference to the strongly expressed wishes of many gentlemen interested in the production of life-size direct photographs, he is willing to reduce the smallest proportion for such heads from seven inches and a-half to seven inches. He would have hesitated in making this modification if he believed any inconvenience could arise therefrom; but as the weather, which has prevailed since his announcement was issued, has been of a character to preclude the prosecution of important photographic work, he feels that no risk exists of negatives having been already produced of the larger size. A formal and detailed announcement of the modification will appear next week.

#### Correspondence.

##### THE MEETING OF THE PHOTOGRAPHIC SOCIETY.

SIR,—I have been informed that in my absence, after leaving the meeting with the council on Tuesday evening last, my name was added to the list of a committee nominated by the requisitionists to reconsider the laws of the Photographic Society. I take the earliest opportunity of declining that honour, and I ask the favour of your columns to give publicity to my refusal to be identified with a disaffection which I entirely disapprove, and with which I have no sympathy.—Yours truly,

W. DE W. ABNEY, Capt. R.E.

DEAR SIR,—Having been informed that after the retirement of the president and council from the meeting last night, it was proposed that I should be placed on the list of a committee appointed, may I ask you to afford me the opportunity of saying that I most decidedly decline to accept such a position. I repudiate entirely the action of the requisitionists, and am sorry that they should have disregarded the wise and prudent counsel of some of the speakers, who, equally anxious with themselves for the welfare of the Photographic Society, desire reform, but dread revolution. I feel that a great mistake has been made, and fear that the result of last night's voting will prove most mischievous.—I am, dear sir, yours truly,

FRANCIS BEDFORD.

326, Camden Road, N., Feb. 11th.

SIR.—It was with feelings of deep regret that I witnessed the late president of our society leave the chair on Tuesday evening, followed, as he was, by the members of the council; although, after the provocation and implied insults to which both he and they had been subjected during the evening, no other course was open to them than to resign.

The organization of the requisitionists—more than the merit of their proposal—enabled them to carry their point at the cost of the disorganization of the society. The motion "that the resignation of the president and council be accepted" was certainly carried by the majority in the meeting, but these, I think I may venture to say, scarcely represent the society generally. However, be this as it may, we have lost our much esteemed president, who has served us ever constantly and faithfully; and I think the least that we can do now is to offer him an expression of our regret at parting with him, and an acknowledgment of our appreciation of the very valuable services he has rendered to the society.

I feel sure that many of our members must entertain similar feelings, and if the idea could be carried out in the shape of a memorial, they would willingly sign it.—I am, yours truly,  
*Strauberry Vale, Finchley, Feb. 12.* ROBERT HAYWARD.

### THE PHOTOGRAPHIC SOCIETY.

SIR,—I beg most respectfully, but earnestly, to protest against the columns of a first-class scientific journal, such as yours, being overlaid week after week with the unseemly discussions of a local clique. Whether one member be not re-elected because his attendance at the meetings of the Photographic Society of London has not been as frequent as expected, or whether another be not elected because he is not popular; or whether the presidency be for life, or for one or more years, may doubtless be of vastly grave import to the Photographic Society, individually and collectively, but is really of no moment whatever to those without the harmed circle.

We provincials look eagerly forward to our weekly News for instruction and amusement, and for the elucidation of the principles and practice of our art; also for reports of the proceedings of home and foreign societies; and these, I imagine, are the chief, if not the only, legitimate objects of such a publication.

I am not aware that the photographic public lies under such a heavy debt of gratitude to the Photographic Society of London, either in theory or practice, as to induce it to submit tamely to such an invasion of your pages; and in looking over several back numbers of the News I deeply regret that so much space has been wasted (I can use no other word) upon a subject entirely foreign, as appears to me, to the normal design of a scientific journal.

In saying this much I am but the faint echo of a sentiment rapidly growing among your numerous country readers.—I am, sir, your obedient servant,  
 R. M. S.

[Our correspondent certainly possesses some grounds for his protest. We can merely plead in extenuation the fact that the Photographic Society has a representative position, and, if in its annual exhibitions only, does much for the advancement of photography. The agitation is doubtless, as our correspondent suggests, due chiefly to the action of a local clique, and it is possible that we have given the matter more space than it deserves. If our readers knew how much we are compelled to reject in such controversies, they would better understand an editor's difficulties. They are not likely to be troubled much further on the subject, as there is little left to squabble for.—ED.]

### PRINTING BY CONTINUATION.

SIR,—I notice, in the last impression of the PHOTOGRAPHIC NEWS, an article on "Printing by Continuation." Now as a printer of some years' experience, I have arrived at the conclusion, that not only does this occur in pigment printing, but also, to a certain extent, in the ordinary silver process. I have frequently put away in a dark room over-night, where no light could possibly get at them, frames containing nearly printed pictures, and found on looking at them next morning that they were sufficiently printed to be taken off without further exposure; this, too, without any discolouration of the paper, as that might be urged as having something to do with a picture appearing to be more heavily printed. Up to the present my investigations have failed to give any satisfactory result, but I think some rather important discovery might be made in this direction, were some more scientific persons to give their attention.—I have the honour to remain, yours respectfully,  
 J. NORTHAM.

*St. Donat's Road, New Cross, February 7th.*

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

A SPECIAL meeting of this society was held, in accordance with announcement, on the evening of Tuesday, February 10th, in the Architectural Gallery, Conduit Street, at half-past six o'clock, Mr. J. GLAISHER, F.R.S., president of the society, in the chair.

The CHAIRMAN briefly explained that the council had received two requisitions, the first of which was informal; the second being in accordance with the rules, the council had called the special meeting to consider its propositions. He might add that he had always been conscious that the laws were capable of improvement, but as president it had been his duty simply to carry them out.

Without further prelude he would now call upon Mr. Whiting, as the first signer of the requisition, to bring forward the resolutions.

Mr. HUGHES requested permission to take the place of Mr. Whiting in moving the resolutions. In a long and aggressive speech he proceeded to impeach the council, to explain his view of the reasons for reform, and to show how he thought the new rules proposed by the requisitionists would effect reform. He stated that in the first place, twenty members sent to the council a requisition to call a special meeting to re-consider the laws. They were not bound to state details, but they had attached a memorandum to the requisition, saying the object would be to alter Rules V. and VII. The council were bound by their own rules to call the meeting; but they did not, and to this moment they received no answer to that requisition, and members present in the council had told them how obstructively it was received. A second requisition was sent, giving the details the absence of which they had understood was the ground of objection to the first, and the council had generously accorded them an hour and a-half to discuss the general revision of the laws of the society. It had been suggested to him that the proper course for him was to propose a vote of censure upon the council—

Here faint applause was heard, and the speaker, accepting the demonstration, observed that such a course would be unnecessary, as the voice of the meeting endorsed the suggestion. A general burst of laughter greeted this joke of regarding the stamping of two or three feet and an umbrella as the voice of the meeting. After a protest from the chairman as to this assumption, the speaker resumed, and explained that in the present system it was possible for members to remain indefinitely in office. One had been in the council for sixteen years (hear, hear, and a cry of "Shows that he sticks to his duty"). Another had been in eighteen years, and was now a candidate for election; but they never saw him at the society. It was necessary to alter this, and by public nomination by members, and non-eligibility for re-election for twelve months after retirement, they hoped to secure this. He moved the adoption of the two new laws, V. and VII., of which notice had been given.

Dr. MANN seconded the resolution, and said, personally, he would have been glad to see the amendment of the council take the place of the resolution; but under existing circumstances he feared a different course must be adopted. He had been told that this movement had its origin in two or three persons disappointed at not receiving medals, two or three disappointed at non-election on the council, and a few generally discontented persons; but the meetings he had attended of those organizing this movement led him to a different opinion. He found a general opinion prevailed that the council wanted to keep this matter from general discussion; and as the committee proposed in the amendment must report to a general meeting, and the matter would thus be practically indefinitely postponed, he gave his support to the resolutions. Dr. Mann then proceeded to refer to the council having placed his name as retiring from the office of vice-president, and alleging that it was in the order of seniority. It was true he did stand in the order of seniority, but he did not believe that it was for this reason he was placed on the retiring list. He was not present at the council meeting at which this was done, but he was told by a friend who was present, in whose probity he had the highest confidence, that considerable discussion preceded his being placed on the retiring list, and that it was not on account of seniority that he was placed there.

The CHAIRMAN here rose and said he must at once correct such a mis-statement. He pledged his word that it was for seniority alone that Dr. Mann was placed on the retiring list, no other motive of any kind having been hinted in the council by anyone.

Dr. MANN was bound to accept this explanation, and in such a case to approve of the conduct of the council; but in Mr. Hughes's case, whom it was believed would have been nominated by the council—

The CHAIRMAN again rose and stated that Mr. Hughes's name had been proposed by himself, and, after three ballots in the council, had been rejected by a majority; but not one word of discussion or influence of any kind was used.

Dr. MANN then briefly seconded the resolution.

Mr. HENRY WHITE then moved the amendment of the council, that a committee be appointed, to consist of six persons, nominated by the members generally, and three to be nominated by the council, to revise the laws, and report to a general meeting. He expressed a conviction that the laws would bear revision, but thought it would be generally agreed that piece-meal legislation was dangerous, and proceeded to point out the anomalies which would be introduced into the laws if the two new rules were

carried and the remainder left as they were. The introduction to the laws would be contradicted by the new laws. He further pointed out the difficulties which arise from the necessity, involved in the proposed new laws, of being compelled at the end of every three years to change the treasurer, just as he was perfectly master of all the details necessary to secure his most perfect efficiency for his office. He had himself acted as treasurer for seven years, and knew much better than those who had not undertaken the responsible task, what difficulties could arise. He believed that he was the person referred to as having been fifteen years on the council; seven of these years he had been treasurer, all through the trying times of the society's financial difficulties. To return to the question of the laws. He believed they might be improved. It was an old question, which had been mooted almost from the time of the infancy of the society. Once a new code had been printed, and, after considering them, the late Chief Baron declared his conviction that the old ones were better. And that was the difficulty: all the new rules proposed had been found, on consideration, less perfect than the old ones. This was most undoubtedly the case, in his conviction, with the new rules proposed now. He remembered that in the original laws of the society some of the provisions resembled those in the resolutions now proposed, and it was found desirable to alter them. One especial point which required revision in the laws was found in the fact that country members had no voice in the society. This was an unquestionable grievance, but one which the new rules of the requisitionists did not propose to remedy. In fact, in this respect the old laws were better than the proposed new ones. By the old ones country members could nominate officers by sending names in writing. By the proposed new ones of the requisitionists they could neither vote nor nominate, for nomination was only to be done personally in public meeting. It could not be doubted, he thought, that a general revision would be better than a partial one, and therefore he proposed the amendment appointing a committee with that purpose in view. He would just say one word on the subject of the requisitions, the facts of which had not been stated accurately by Mr. Hughes. By Law VI. twenty members could require a special meeting to be called without stating any purpose. But the requisition did state a purpose—the alteration of laws—and by Law XI. it was enacted that no meeting could be called for alteration of laws without stating the precise alteration to be proposed, that due notice could be given to every member. The requisitionists did state their object to be alteration of laws, but did not state the nature of the alteration proposed. Hence their requisition was not in accordance with either Law VI. or Law XI, and the council had no alternative but to decline acting upon a requisition so framed. It was unanimously agreed, therefore, to invite a deputation from the requisitionists to confer with the council as to the precise object in view, in order that it might be brought before the members without the delay contingent upon framing another requisition. Three of the gentlemen associated with the requisitionists were present at the council, and these gentlemen joined in that unanimous resolution which was now styled treating the requisitionists with contempt. The requisitionists sent no deputation, but sent another requisition, which had been duly acted upon. He concluded by pointing out the evils of personal nomination, and the advantages of written nomination available for every member in the society, all of whom ought to receive voting papers, so that country members as well as town members would be duly represented in the management of the society. These and other advantages might be secured by the committee proposed in the amendment, which he would now propose.

Mr. F. BEDFORD begged to second the amendment.

Mr. WALTER BIRD, as one of the first requisitionists, had not felt that they were treated with sufficient consideration. He added that, much as he esteemed the position of the chairman, and respected the firmness often necessary in his office, he thought that the power of the chair was at times brought to bear too strongly upon individual members.

The CHAIRMAN said he was utterly taken by surprise by the remarks just made. He had been so constantly greeted with expressions of kindness and approval on all hands, that he certainly never anticipated such a charge. In fact, their meetings had hitherto been so pleasant, that he never remembered, until the last meeting, having had occasion to call any one to order. At the last meeting he was compelled to repress an irregularity on the part of Mr. Stillman, who challenged the accuracy of the minutes of a meeting at which he was not present. The question to which he referred as omitted from the minutes was irregular. The secretary had no power to answer the question. He, as

president, might have instructed the secretary to give the desired information, and should have done so; but the question was irregular, and its omission from the minutes was not an inaccuracy. In any case, every gentleman must know that Mr. Stillman's objection was irregular, and his offer of a printed journal was one the chairman could not accept. Regarding the requisition and the complaint about its treatment by the council, he was not less surprised. It was received on the 24th of December, and he at once communicated with the secretary to call a council meeting to give it effect. The secretary was absent from home; and being at that time in the midst of Christmas holidays, it was impossible to secure a council meeting for a few days. When they met, every disposition was felt by every one to meet the wishes of the requisitionists, but their requisition was found to be informal; and, acting under legal advice, they found they could not act upon it. They therefore issued a kindly invitation to the requisitionists to meet them, that all might work in harmony. The requisitionists had taken another course; but he felt bound at this point to interpose an explanation.

Mr. SAMUEL FRY agreed that some revision of the laws was desirable, and hoped the discussion would only lead to renewed vitality in the society. He thought that this end would be best secured by the amendment, which he begged to support.

Mr. J. R. SAWYER opposed the amendment, because it proposed to postpone the consideration of the report of the proposed committee to a general meeting, which would involve waiting twelve months.

The CHAIRMAN explained that this was an error; no necessity for such waiting existed, nor any idea of such a thing.

Mr. GEORGE HOOPER, as an independent member, strongly protested against a body of twenty or thirty members—requisitionists or otherwise—meeting in private to make laws, bringing them to a meeting cut and dried, and urging the meeting, without further time for consideration, to carry them as laws of the society. He objected also to a plan which turned the president from his office at the end of three years, and no matter how perfect or how useful, prohibited the society from electing him again. He objected to a number of men combining to cast slights upon officers who had brought them through troubles into a prosperous condition—gentlemen who had done all the work of the society, and produced the bulk of the papers read. If members felt blame existed anywhere, let it be placed on the right shoulders—their own—for anything of which they had to complain was due to their own supineness. He objected to a scheme which cut out country members from all voice in the society. And whilst he objected to all this, he would ask, who are these twenty or thirty members, and what have they done for the society, that they should meet in secret to frame laws for the society, and urge their acceptance without the consideration to which they would be submitted in a committee such as that proposed in the amendment, which he would support?

Mr. CHERILL wished to say a few words from a country member's point of view. There were, he believed, upwards of 200 such members in the society, and the gentlemen who were called the requisitionists seemed to have ignored them entirely. They were, in fact, more completely ignored by the new rules of the requisitionists than they were by the old rules of the society. He could not but think that it was a lame and imperfect movement which ignored upwards of two-thirds of the members. He should earnestly support such an effectual revision of the laws as the amendment seemed to contemplate; but he could have no confidence in the promise of a revision by those who opposed that amendment. It was very strange that, as several of those connected with this agitation had been members of the council, not a word, not a suggestion, of the need for reform was heard from them whilst there; as long as they were in power they said nothing of the need of reform. Now the council which dispensed with their services was found to be a self-elected and self-seeking body! If the council really were self-elected, it was the fault of the members, who had the power of nomination. But his opinion was, that the reason the members had not exercised the right of nomination was simply due to the fact that the council list had always consisted of the very best men for the office, and to the fact that the members at large had full confidence in the council. The new rules proposed by the requisitionists appeared to involve three principles, all of them, in his view, open to objection. First, nomination of members of council in open meeting by members. This could be done already, and something more, for written nominations now could be made as well. Second, the three years' system. They had the power now of retaining officers three years; but it appeared to him singularly unwise to render the retention of an unsuitable officer for three years imperative,

whether he was valuable to the society or not. But however valuable an officer might be, according to the requisitionists, at the end of three years go he must. And he must confess that this provision appeared, in his opinion, aimed at their present admirable president. The third provision seemed to have a similar tendency. At the end of three years the best possible officer must go, although they might be keeping on an inefficient one three years. He earnestly supported the amendment, because it gave power to secure a thorough revision of the rules. It appeared most liberally framed, for it gave the requisitionists power to nominate six members, and the council only three, so that the council nominees manifestly had no power of out-voting the committee generally.

Mr. F. HOWARD urged the meeting to adopt the proposed laws of the requisitionists as an instruction to any committee.

CAPTAIN ABNEY said that the amendment proposed by the council, and the committee which the requisitionists proposed to ask for at the general meeting, might practically issue in a similar result, namely, a revision of the rules. But there was a wide difference in what would be implied by the two things. If the amendment were carried, the society and its existing council would be working in harmony to a common end; but if it were rejected, in order to appoint a committee on a different motion, it would imply a slight on the council, and a determination not to accept their co-operation in securing such a revision of the rules as might be beneficial to the whole society.

Mr. STILLMAN opposed the amendment, because it appointed no time to report, and gave no instruction to a committee.

Mr. HARR agreed that country members ought to be represented, and said that could be arranged for afterwards if the new rules were carried.

Mr. MAYALL thought really but little difference existed between the professed aims of both sides. The council said the laws wanted revising, and the requisitionists said the same thing. But the subject required careful consideration, as the proposed new laws plainly showed. They were certainly not well digested, although he agreed with them in some points. It was not surprising that after a society had been in existence upwards of twenty years some of its laws should require revision; but he could not understand the objection to an amicable arrangement of the matter. The council made a suggestion that seemed beyond question. They proposed a committee in which they offered the opposition six members as against three to be nominated by themselves. He hoped such a committee would be accepted, and that, as Mr. Cherrill had suggested, a recognition of country members would form one of the provisions.

COL. STUART WORTLEY intended to vote for the amendment. In the Royal Society, in the Royal Academy, in every society with which he was acquainted, it was the custom for the council to furnish a house list of nominations for the new members of council, and he saw no reason why the Photographic Society should give up the benefit of the precedent which was found to work well in other learned societies. It was manifest that a council which had been devoting time to carrying on the business of the society must have a better idea of those who ought to retire, and whom it was desirable to elect, than many who had never thought about the subject. The society had always the privilege of rejecting the house list and proposing others. Further, he felt that it was not wise to compel the society to give up a president, however efficient, at the end of three years. He did not, however, think that it was intended as an attack upon the present president, whom he believed every one regarded with esteem.

Mr. HUGHES, in reply, said he protested against the appointment of a committee without any instruction of any kind.

Mr. SEBASTIAN DAVIS interrupted to point out that the preamble to the amendment distinctly recognized the principle which the requisitionists were contending for, only suggested that a still broader principle should be acted upon.

Mr. HUGHES, in reply, said that the council objected to their first requisition on the ground of vagueness. He objected to the council's preamble to the amendment on the ground of vagueness, and urged upon the meeting to carry the resolutions as a definite instruction to any committee that their revision had to include the primary principles of the resolutions. He objected to the council's amendment because of its constitution, and asked what right the council had to claim the nomination of any of the committee, especially without first submitting their names to the meeting. The council wished to have the nomination of three dark horses—three unknown men.

Mr. BLANCHARD asked if the council consisted of unknown men?

Mr. HUGHES resumed, that he further objected that reporting to a general meeting left the matter over indefinitely, as the only general meeting was the annual meeting. He urged the meeting to vote for the resolutions.

A VOICE.—Every meeting of the society is a general meeting.

The CHAIRMAN explained that in a sense all meetings were general; that it was entirely erroneous that any notion of delay was involved, or could be, as the report of a committee would of course be made to a special general meeting, the present being, in the ordinary course of business, adjourned for receiving such report. After a few further explanations, he put the amendment, and then the motion.

The amendment of the council was lost, and the resolution of the requisitionists carried by a majority of six, twenty-two voting for the amendment, and twenty-eight against it. The chairman said they would now proceed to

#### THE ANNUAL GENERAL MEETING.

The minutes of the last general meeting having been read and confirmed,

The TREASURER read his report, which showed a balance in hand of upwards £170.

The PRESIDENT expressed his pride and satisfaction in such a report, and referred to the difficulties through which the council had, during the last few years, happily conducted the society. From having a deficit of £500, they now had £300 to the good which might now be used for the benefit of the society and the art. He would now call upon the secretary to read the report of the council.

The SECRETARY then read the report, which gave an interesting résumé of the proceedings of the society, and of the progress of photography during the past year. The report having been received and adopted,

The CHAIRMAN said that the duties of the council for the past year now being completed, he should be wanting in self-respect if he remained any longer president of the society. By the vote of that evening, and the terms employed, it was manifest that the council and himself no longer retained their confidence, and in the name of the council, who had asked him to represent them, and himself, he tendered the resignations of its officers into the hands of the society. He thanked them for many expressions of past kindness, and hoped for the society every success in the future, and a better president and better officers. He would now vacate the chair, which, perhaps, Mr. Hughes would come and fill.

The PRESIDENT then left the room, accompanied by members of the council. For a short time bewilderment and confusion ensued.

Mr. STILLMAN moved that the resignations be not accepted.

Mr. MAYALL said: You cannot help accepting them. This is what your success has brought you. You have passed a vote of want of confidence, and then you talk of not accepting the legitimate consequence. Such a position is perfectly ridiculous.

Col. WORTLEY protested against the word ridiculous.

Various voices were heard suggesting various things. Mr. Bedford was nominated to take the chair by one, Mr. Davies by another, and Dr. Mann by a third. Some one then remembered that the president had ironically invited Mr. Hughes to the chair, and that gentleman proceeded to undertake the office. After further uncertainty and confusion,

Mr. HUGHES proposed to proceed with the ballot for officers.

Col. WORTLEY protested against the balloting papers as illegal, as they did not contain all the names proposed. The names of Mr. Hughes and Mr. Dallmeyer had been proposed, and did not appear in the lists.

Mr. HUGHES said that he had written to the secretary to decline; as he thought, under existing circumstances, it would be unbecoming of him to accept office.

After further conversation,

Mr. WALTER BIRD moved that the resignations be accepted.

Mr. STILLMAN seconded the motion.

A general conversation followed, condemning the council for want of respect and consideration to the requisitionists in having resigned. One gentleman affirmed that when a Ministry resigned, it always held office until another was formed.

Col. STUART WORTLEY emphatically affirmed the contrary, saying that when the Cabinet resigned, it did so completely and at once. The comments on the council now that they had retired were very unfair. They had the perfect right to resign, and had acted as men of any feeling of self-respect must have done. The most that now could be done was to pass an amend-

ment to the last motion, asking the council to reconsider their decision, and retain office for the present.

Mr. HOOPER seconded this amendment. The original motion was carried by 16 against 13.

The CHAIRMAN again proposed to go on with the ballot.

Col. WORTLEY again protested against the balloting as illegal.

Mr. STILLMAN proposed getting a legal opinion.

After some further confused conversation it was proposed to elect officers at once without nominations.

Mr. W. BIRD proposed Dr. Mann as president, and Mr. Goslett seconded him.

Dr. MANN declined, under the circumstances, to stand.

Mr. HUGHES again proposed to proceed to the ballot, saying that if they elected the five duly nominated at the last meeting, these being appointed could fill up the vacancies caused by all the resignations, as an addendum to Rule VII., passed in 1856, gave them power to do. Whilst the ballot went on they would proceed with the appointment of a committee.

Mr. STILLMAN moved that a committee be appointed to revise the laws, and that Mr. Hughes be empowered to nominate the members.

Mr. HUGHES said that as they had themselves objected to the council proposing to nominate three out of nine, it would not be wise to give him the power of nominating the whole committee.

Dr. MANN seconded the resolution, and suggested that the number be nine. To this Mr. Stillman agreed, and the motion was carried.

The following gentlemen were then proposed and elected:—Dr. Mann, Mr. Hughes, Mr. Stillman, Mr. Sawyer, Mr. Bird, Mr. Hart, Mr. Werge, Col. Wortley, and Mr. Thomas. Mr. Sebastian Davis, Mr. Wharton Simpson, and Mr. Pritchard were nominated, but declined to act. Mr. Englaud, Mr. Bedford, and Captain Abney were elected in their absence.

Mr. STILLMAN proposed that the committee report on March 10th.

Mr. HUGHES asked if it would not be better to avoid naming any specific time for reporting?

It was agreed that the meeting be adjourned to March 10th, when the committee would report progress.

The returns from the scrutineers gave the following as the present officers of the society:—*Vice-President*—Mr. J. R. Johnson. *Council*—Dr. Mann, Mr. J. A. Spencer, Mr. W. Woodbury, Mr. F. Howard, and Mr. Goslett.

Mr. HOOPER wished to say, before the meeting separated, that if, as had been declared, the vote of the requisitionists was not intended as a vote of want of confidence, the only way to prove it would be to take some steps for the re-election of Mr. Glaisher and the council. He was satisfied that only by some such step would Mr. Glaisher be induced to return, and he did not know where they would replace him.

After some further conversation the meeting was adjourned.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this society was held in 5, St. Andrew Square, on Wednesday evening, the 4th inst., the president, Mr. R. G. MUIR, in the chair.

The minutes of previous meeting were read and approved, and the following gentlemen admitted ordinary members:—Messrs. John Legget, William Anderson, John Stenhouse, D. Finlaysou, W. B. Wise, and D. C. Simpson.

Mr. J. M. TURNBULL read a paper "On the Keeping of Sensitized Paper" (in our next), and showed a number of specimens, both of paper and prints, in various stages of manipulation.

Mr. PANTON had used Durand's paper for a considerable time, and found it perfectly white, and remain good for several months, if kept under pressure.

Dr. THOMSON had frequently used preserved sensitized paper, and found it answered his purpose admirably; he had some now in his possession that was sensitized in July last, and was still as white as ever, and printed well. In its preparation two baths had been used: the first, a 60-grain solution of silver, which thoroughly coagulated the albumen, and converted the chlorides of the alkaline metals into chloride of silver; and the second, a 20-grain solution of silver, containing 25 grains of citric acid. The citric acid, he said, prevented discolouration of the paper, and gave it its keeping properties. Before printing, however, he considered that it was absolutely necessary to fume with ammonia, to get rid of the citric acid; and he had no doubt that

if Mr. Turnbull had tried the fuming, he would have found his paper answer better. The fuming generally discoloured the paper a little, but the darkening entirely disappeared in toning.

Mr. BASNFORD had used the collodio-chloride paper a good deal, but it discoloured rapidly, and had to be given up.

Mr. PRINGLE said that it was no doubt desirable to get a paper that would keep good for some time, but he thought it more important to know how to use it properly. Some people seemed to think that printing was merely a mechanical process that could be done by anybody, and that all that was necessary was good paper and a fair negative. He believed that there was more art required for really high-class printing than was generally conceded, and thought that photographers generally did not give it the attention it required.

The PRESIDENT said the subject was one of such interest that it could not be fairly discussed off-hand, and suggested that the discussion be adjourned, to enable members to experiment, and bring up results at a future meeting. (Agreed.)

Mr. TURNBULL then introduced a lamp which he had constructed as an improvement on that used in the sciopticon. The improvement consisted in the introduction of a third wick standing thus  $\angle$  between the two angular ones. His object was, first, to increase the light; and secondly, to get rid of the dark shadow which the sciopticon, as at present arranged, casts on the upper part of the screen. The increase of light was very marked, but, unfortunately for the success of the lamp, the shadow on the screen was rather intensified.

Several modifications were suggested with a view to get rid of the shadow, and it was understood that the subject would be again introduced.

After the usual votes of thanks, the meeting adjourned.

### Talk in the Studio.

**FIRE IN A STUDIO.**—On Saturday evening week, a fire occurred in one of the studios of Messrs. A. and J. Bool, through the servant cleaning the room by candle-light. It is supposed that a spark must have caught some of the canvas scenery, or carpet, for about an hour afterwards the neighbours gave an alarm, and the scenery and blinds of the roof were found in a blaze. Having, fortunately, some water at hand, the fire was soon put out, without damage to cameras, lenses, &c., which were in the studio. The damage (about £30) is fortunately covered by insurance.

**PREPARATION OF BROMIDE OF AMMONIUM.**—In a recent communication to the *Pharmaceutical Journal* Mr. Price gives the following as a convenient mode of preparing the bromide of ammonium required by photographers:—Take four ounces (troy) of good bromide of potassium and dissolve it in six fluid ounces of boiling water; next dissolve three ounces (troy) of sulphate of ammonia in four and a-half fluid ounces of boiling water, and then mix the two solutions. Double decomposition now takes place, the result being the production of bromide of ammonium and sulphate of potassium. The latter salt is sparingly soluble in water, and still less so in weak alcohol; hence Mr. Price recommends that one and a-half fluid ounce of alcohol should be added to the cold liquid, and the whole then allowed to stand for twenty-four hours. The greater part (nearly all) of the sulphate of potassium will then be found to have crystallized out. The whole is filtered, washed with a small quantity of a mixture of one part of alcohol and four of water, and the filtered liquid then evaporated to dryness. The bromide of ammonium so produced keeps well, and is free from sulphur—a not uncommon constituent of a bromide made from hydrobromic acid prepared by the action of sulphuretted hydrogen on bromine in presence of water. We need scarcely say that the presence of a trace of sulphur would produce spots and stains in the sensitive photographic film prepared from a collodion in which the impure bromide had been used; and we have little doubt that some apparently unaccountable stains traceable to the collodion are often really due to the impurity of the salts used in bromizing the liquid.

**NEW METHOD OF MOUNTING STEREOSCOPIC VIEWS.**—By *Professor Himes.*—Instead of affixing the photographic prints to the usual stiff cards, they are mounted in a book about  $3\frac{1}{2}$  by  $2\frac{1}{2}$  inches, on leaves of heavy paper of double that size,

fastened by their centres on short guards, like maps in an atlas: each book containing about a dozen such double leaves. A piece of smooth paper is placed between the halves of each stereograph after mounting, and the book subjected to pressure, as of a copying press, for an hour or more. By opening such a book at any of these double leaves, and sliding it between the wire guards of a Holmes stereoscope, like an ordinary stereograph, an effect equal in all respects to that of the card stereograph is produced. Since the pictures can be readily examined by simply turning the leaves, and may be compactly stowed away, it is claimed that there is comparative freedom of the photographs from injury by mechanical, chemical, or atmospheric influences, whilst the facility of reference to any particular picture is greatly increased, especially when collections are properly arranged and classified, for which purpose each book is supplied with blank index and title pages. It is suggested that collections of stereographs on this plan, illustrative of different subjects, scientific and otherwise, or supplementary to books upon such subjects, might be placed in libraries, accessible to the public, with almost as little risk of injury as the books; a few simple instruments hung near such cases being the only addition necessary. The range of purely scientific subjects susceptible of stereoscopic illustration might increase under such encouragement.—*Journal of Franklin Institute.*

**TO SAVE OVERPRINTED PHOTOGRAPHS.**—Tone and fix in the usual way. Having taken out all sufficiently light, turn off the hypo fixing solution, and wash in one or two waters; then turn on to the prints a very strong, fresh solution of hyposulphite of soda in water quite warm; watch closely, and remove as soon as light enough. If very dark prints are to be bleached, don't overtone, as they will look more toned after bleaching. Prints bleached in this way will come out as brilliant as when printed right, and fixed in the usual way. I have tried several formulæ, such as cyanide, ammonia, &c., but the prints were spoiled in tone and brilliancy, also the paper turned yellow.—*J. SAUNDERS, in Philadelphia Photographer.*

**TO DUPLICATE NEGATIVES BY THE WET PROCESS.**—Place upon each corner of the negative to be duplicated a piece of cardboard sufficient to keep the coated and sensitized plate from touching against it. Place this in the plate-holder, and upon it an ordinary wet collodion plate, and close as usual. Place the camera in good light, with two thicknesses of tissue-paper over front of lens; slide the bellows as close to lens as possible, and be able to cover the plate; expose about the ordinary time for a negative in the usual way; develop; and you get a nice sharp transparency, and from this you can make as many negatives as wished in the same manner, or enlargements can be made as with other transparencies.—*Ibid.*

**REMOVING IODIDE FROM BATHS.**—*Mr. S. M. Miller, writing to our Philadelphia contemporary, says:—*"I have made a little discovery (new to myself at least) in regard to clearing old baths of iodide. Let the bath get almost cold enough to freeze, and the iodide will form in the shape of very fine crystals, which are easily filtered out. I find the method very simple and effectual, especially in winter. When summer comes, I shall adopt the plan of packing my bath in ice, to produce the necessary degree of cold. This may be old to you, but I find it a decided saving of time and labour over the old method of diluting, filtering, and evaporating."

## To Correspondents.

*J. M.*—The best mode of removing stains or dirt from the surface of a lens consists in the application of dilute sulphuric acid, one part of acid to two parts of water. Rub gently with a piece of woollen cloth, and then rinse.

*J. FRANKS.*—We have no knowledge from experience, but believe the exposure is very much longer. The maker will doubtless give you a satisfactory comparative statement of the difference in exposure.

*BACUP.*—Without knowing the nature of the impurity it is difficult to give a suggestion as to its removal. Are you sure that the yellowness is the result of the washing water? If the impurity of the water be due to organic matter, which is most probable if the water has a yellowish brown discolouration, Condy's fluid (permanganate of potash) will purify it. Try that. Boiling will aid in removing many impurities. Try it. 2. You may obtain carbon enlargements of Messrs. Spencer, Sawyer, and Bird, at their printing works at Ealing.

**NORTHUMBERLAND.**—You can scarcely have read all that has recently appeared in our pages on the subject of enlarged negatives. There are two plans strongly advocated by successful enlargers. One plan consists in producing a transparency the same size as the negative by superposition, either on carbon transparency tissue or on an albumen plate. From a good transparency so obtained from a good negative you may secure a good enlarged negative. The other plan consists in taking an enlarged transparency, and carefully working upon this to remove defects and soften coarseness. From this transparency you can also secure a good enlarged negative. But you employ neither plan. You produce a small transparency in the camera on wet collodion, and from that an enlarged negative in a similar manner, and you obtain a coarse result. This is the usual result under such circumstances. Every defect in the original negative and the transparency is magnified, and the coarse texture and the coarse deposit of an iron developed image on wet collodion are magnified. With a very fine negative of a very refined face you may, by your plan, obtain something pretty good. Read carefully the recent papers and discussions, and follow out the hints given. The portrait you enclose is wanting in sharpness, and is too abruptly lighted. The shadowed side sadly wants reflected light.

*I. W.*—A good landscape lens or a triple will answer well for all the purposes you mention.

*T. T.*—Unless you have some knowledge of German pronunciation, you will scarcely speak the name with absolute precision; but it is pronounced very nearly as it would be in English, giving, however, the sound of *oo* to the *u* in the first syllable of the surname. *JOHN BULBECK.*—There is no work on lighting except that of Bigelow, which is, however, a very good work. Robinson's "Pictorial Effect" also contains much information on the subject. Perhaps, on the whole, you will find it more generally useful.

*J. W.*—The general lighting of your pictures is not bad, but the negatives are over-intensified, and the prints not quite deep enough. The reflections from the white paint on the south side seem in some somewhat too strong. We should in such a room have blinds fixed at the ridge for the skylight, and curtains sliding on rods for the side lights. The lens you mention would answer well for such work. You may at times find the lenses of the maker in the hands of second-hand dealers, and you may safely purchase there. We highly approve of Weston's Burnisher.

*A. H.*—A pencil drawing may be copied by the wet process with perfect success. Do not over-expose the plate, and develop with a weak iron developer, say five grains of the iron salt and fifteen minims of acetic acid in an ounce of water. If the solution is somewhat old, so much the better.

**DEAF AND DUMB ARTIST.**—Thanks. In our next.

*W. R. F.*—Thanks. The paragraph is amusing enough, as illustrating the want of familiarity with the art in many journalists. The Vander Weyde process is referred to in the first part, and the lens of extraordinary power is the very large condenser of Monckhoven's enlarging apparatus.

*H. W. D.*—You do not seem to realize the distinction between the amount of a salt contained in a measured ounce of a saturated solution, and the amount which must be added to an ounce of water to saturate it. When you have added six drachms of protosulphate of iron to an ounce of water, you will have saturated that water; but you will have considerably more than an ounce of saturated solution, although by measure you will not have an ounce and six drachms. If you wish to enter fully into the details of this question of saturated solutions of iron salts, you must refer you to Storer's Dictionary of Solubilities, where you will find it treated at much greater length than we can treat it here.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### SPECIAL CORRESPONDENTS—DUMMIES IN THE STUDIO—THE WAR ON THE GOLD COAST—THE TRANSIT OF VENUS OBSERVATIONS.

*Special Correspondents.*—"I certainly must get a pocket camera!" a well-known artist exclaimed in our hearing the other day. He had been to St. Petersburg on behalf of the principal illustrated London paper, sketching at times with might and main to secure a pictorial record of the interesting scenes going on around him. The subject points of a group, or the central portion of a ceremony, his rapid pencil could cunningly sketch all in good time; but then the general aspect and surroundings were not done justice to, and it was in this respect that he sorely needed assistance to give a proper reflex of the same. Thus in the ceremony of "Blessing the Neva," or "The Royal Marriage," if, as he explained, he had had an assistant to expose for him a dry plate, and thus secure an outline (no matter how rough or indistinct) of the whole display, he would have been able to have furnished a much more truthful representation, because the surrounding details would have been correctly put in. Had he been thoroughly accustomed to Russian scenes and Russian costumes, background and accessories might, it is true, have been imagined when finishing off the sketch; but in any case a rough photographic cliché would have been of the greatest aid in producing the block. The time may not be very distant, therefore, when we shall see special correspondents not only provided with a trusty field glass, but carrying a *reconnoisseur* camera, with instantaneous dry plates, which will furnish at home as much matter for descriptive articles as the whole mass of manuscript notes or pencil sketches they have taken.

*Dummies in the Studio.*—Dummies come out so very truthful in photography that their aid is seldom invoked by the professional photographer. Dress a doll up any way you like, it will never be mistaken for a baby; and if you really want to prove that a stuffed animal is really what it appears to be, you have only to photograph it and show the result. Therefore we think that few answers will be received by a Coblenz photographer who advertizes in the *Archie* that he has for disposal "a wooden horse, life-size, accurately modelled from nature, provided with saddle and bridle complete. The horse is well suited for a garrison town where cavalry are stationed."

*The War on the Gold Coast.*—Although statements have appeared in our contemporaries to the effect that photographic apparatus in some quantity has been shipped to the West Coast of Africa, we fear that no official steps have been taken to secure photographic records by Government. Mr. Pritchard, of the Woolwich Photographic Establishment, as also Captain Abney, R.E., who conducts the Photographic School at Chatham, are both unable to give us any information on the subject, and the inference is that if any apparatus has been despatched, it is private property. That several of the officers engaged at the scene of war have provided themselves with cameras and the necessary requisites, there is little doubt, for photography is a favourite pursuit with many in the army, and this would be too good an occasion to pass over; therefore we may at any rate rely upon some photographic records being secured. It is, however, very much to be regretted that the Government, in restricting the non-combatant element to the narrowest limits, did not spare a couple of men to act as photographers. Pictures of well chosen subjects would have been invaluable hereafter as records, and would form the most important portion of any history that may be written on the subject, for the natural difficulties and peculiar features of the country would thus be most graphically portrayed.

*The Transit of Venus Observations.*—As we stated a little while ago, Dr. Krone, the President of the Photographic Society of Dresden, has been instructed by the German Government to make the photographic observations of the transit of Venus at a station on the Falkland Islands, and the distance of the station will naturally necessitate his departure in early summer. The photographers to represent this country are not yet told off, but it is settled that Captain Abney, R.E., goes to Alexandria in charge of the station there. Dr. Vogel, of Berlin, who has had more to do, perhaps, with photo-astronomical observations than any man in Europe, is to take charge of a station somewhere in China or Japan, the locality not being yet fixed. It is to be hoped that the name of Captain Waterhouse, the Assistant Surveyor-General of India, may not be forgotten when choosing photographers to undertake the observations, for that officer, besides being a most accomplished operator, has already acquired special experience in this particular branch of camera work.

### THE RIGHT TO ONE'S FACE.

A RECENT extract from an American paper, given in the *Times*, has again revived a curious phase of the copyright question, and raised the question, has a man a copyright in his own face? It is certain that the statutes relating to copyright make no provision for protecting such a right, and it is somewhat puzzling to decide in what legal form the question could be raised. The case in point has reference to the publication of an engraved portrait; but the practice of photographers of exhibiting specimen portraits is referred to in connection with the subject as open to serious objection. The extract to which we refer is as follows:—

*THE RIGHT TO ONE'S FACE.*—The right of a man to control the publication of his own features is a rather delicate point of personal law which has never been sufficiently elucidated. The well-known practice of photographers in exhibiting copies of the portraits which they have taken is one which, on some grounds, may be deemed open to grave exceptions. The position of the illustrated papers in the matter might also repay inspection. A contemporary, having prepared for publication a portrait of a lady whose husband is in high official position under the present administration, the picture was reluctantly suppressed at the request of the latter on the assurance that it was the lady's wish. At the same time, the journal announced that this was the last time such a concession would be made to private prejudices. It proclaimed the doctrine that neither man nor woman had any property in the reflection of their features, and that hereafter in a similar case it should not "feel compelled to regard the wishes or request of the party concerned." The same journal announced in one of its early impressions that it would give representations of private wedding parties whenever it felt inclined, and that it "should not feel compelled to regard the objections of the parties concerned." In cases like these it is difficult to draw the precise line where liberty ends and license begins; but men of right feeling and true delicacy know by instinct what is correct, and what is a violation of personal rights and domestic privacy. If the portraits thus published in disregard of wishes and requests were uniformly artistic or approximately like, one part of the objection, though not the essential part, would vanish; but they are often such hideous caricatures as to amount to positive pictorial libels. The paper we speak of published, a day or two after his death, what it called a portrait of Charles Astor Bristed. The face depicted might have belonged to a butcher or a drover, but had not a trace of the intellect and high breeding marked in every feature of its pretended subject. It may be said that very few people really object to have their portraits published. That is probably true, yet it is not exactly the point. The question is not whether it is generally right and proper for an illustrated paper to publish such portraits as it may deem of interest to its readers, but whether such portraits may be rightfully and properly published in defiance of the expressed will of their prototypes. It would certainly be a most interesting case for a court of law. —*New York Times*.

Mr. John Leighton, the errors in whose letters we pointed out a few months ago, when the question of portrait

copyright was discussed in the public press, in referring to this question again, takes occasion to repeat the same erroneous statements. He says, in a letter to the *Times* :—

SIR,—It is a lamentable fact that no one in England has a copyright in his own face, the same being at the mercy of any photographer who may seize it. The copyright in negatives, as we know by a late discussion in *The Times*, is vested in the photographer, unless formal stipulations are entered into prior to the sitting.

At the time of the formation of the Art Copyright Act I strongly opposed the immolation of the sitter's rights, and since then the processes and methods of reproduction have multiplied indefinitely, the objections becoming greater—the illustrated papers often taking any print they please, instead of asking the person to sit to their nominee, that they may produce an original and satisfactory picture.

At the period of the death of Madame Rachel, the eminent French *tragedienne*, a Paris photographer managed to obtain access to the mortuary chamber, where he posed the body conveniently, and took several negatives. After this he employed an artist to touch her up, opening the eyes—in fact, to animate the corpse. That, I need hardly say, resulted in a ghastly libel, which stared out horribly in all the print shops, causing the family to proceed against the perpetrator, who was fined and punished, though not until after many had been sold. We should have wanted precedent, but the French laws being codified render justice more facile.—Yours ever truly, JOHN LEIGHTON.

Royal Institution, Albemarle Street, Feb. 14.

It is probable that the English law would have found ready means to punish the perpetrator of an outrage like that described, but, as it scarcely bears on the question of copyright, it is not necessary to discuss it. It is in the notion that the photographer, in the ordinary practice of portraiture, acquires a copyright in the photographs he produces, without the consent of the sitter, that Mr. Leighton's error consists. The Copyright Law distinctly enacts that where the portrait is a commission, produced for "a good and valuable consideration," the copyright does not vest in the artist without a written agreement with his customer. That point relating to the sitter's rights is tolerably clear in the Act; whether the copyright accrues to the sitter without an agreement is not quite so clear, as the Act is very clumsily worded. Some have held that the copyright does, according to the Act, so accrue to the sitter. But whilst this point does not appear certain, it is practically of little importance: for whether, as we are inclined to think, no copyright arises in such case; or, arising, it belong to the sitter, the issue would be much the same, except in exceptional circumstances not often likely to arise.

A further letter has been sent to the same journal by Mr. A. Beau, who proposes to make the custom, now universally recognized, of printing from a portrait negative solely to the sitter's order, more imperative and certain, by registering the copyright, in the sitter's name, at Stationers' Hall, a written agreement being, of course, previously necessary. He says:—

SIR,—May I be allowed a few words on the controverted question of negatives, as it is now transferred to a ground upon which I am particularly concerned?

I am sure no respectable photographer will contradict me when I assert that the rule has always been to keep all private negatives for the sole use of the persons whose likeness they represent, and, moreover, that this rule may be said to have been strictly adhered to.

I would propose a very simple plan of solving the difficulty. It would consist in entering the negative at Stationers' Hall, in the name of the sitter, who would pay the charge of such entry—viz., 1s.—and thus secure the copyright of the image.

For my own part, I am quite ready to offer this satisfaction to any of my clients who may wish it.—I am, sir, your obedient servant,

ADOLPHE BEAU.

283, Regent Street, Feb. 16.

## MY TROUBLES IN TAKING LARGE DIRECT HEADS.

BY R. W. ALDRIDGE.\*

MR. CHAIRMAN and GENTLEMEN,—It is not often that a discussion introduced at these meetings is allowed to extend to a third night. The subject of "Enlargements *versus* Direct Pictures," opportunely introduced by our friend Mr. Croughton, has excited so much interest, as witnessed by the articles and letters in the journals, that I think it would be a pity to let it drop while anything remains to be said upon the subject. Much of this interest is doubtless owing to the recent competition for the Crawshay prizes. The principal speakers upon the two last occasions are both well known as being professionally engaged in enlarging. It is, therefore, not very surprising that they should, even in spite of an old proverb, have treated the matter as if there were only one side to the story. They have certainly enlarged upon the advantages of enlarging. It is to be regretted that none of those gentlemen who have carried off the prizes have been induced to take up the glove on behalf of the direct heads. I feel that I am but half a champion at the most, as I believe that after a certain point the enlarging process has the best of it. This point I am inclined to place at about half the size of life. It is for this reason that I have preferred to entitle this paper on "My Troubles in Taking Large Direct Heads," rather than damage the cause I espouse by my inefficient handling. I have also another motive: I believe that in the last competition the size of the face—or, as it is wrongly called in Mr. Crawshay's announcement, "the head"—namely, from seven and a-half to eight inches, considerably exceeds the average length of the "human face divine," even in male heads. Of course, in the case of the fair sex—always the most attractive part of a photographic display—the difficulty is much greater; so much so as practically to be prohibitive to those who object to the distortion inevitably resulting from making objects larger than the model. By the enlarging process it makes but little difference whether the face is increased to eight or eighteen inches—disproportionate distortion will not be the result; but in the direct heads it is far otherwise. In the discussion that followed the reading of Mr. Edwards's paper, I stated my objections to any comparison between the direct and enlarged heads of the larger than life size. Practically they were both enlargements, and under such circumstances I prefer those that were correctly labelled. I am a believer in large lenses up to a certain point, and it is to prevent their being overweighted in the coming race, as well as the hope that a record of my mistakes may be useful to those who travel the same road, that I have put together these few notes. Much has been said both for and against the proportions I stated as the standard on the last occasion; resulting, however, in an unanimity, on the part of those who took the trouble to submit them to the test of actual measurement, for which I had scarcely hoped. As the subject seems to possess an interest, I will give at somewhat greater length the usually recognized proportions, and the way in which they are applied by artists.

According to the standard proportion, the face is allowed to contain one-tenth of the length of the whole figure, measured from the sole of the foot to the crown of the head. The face itself is divided into three equal parts—or, as we say, into three noses—namely, from the bottom of the chin to the bottom of the nose; the nose itself; and, lastly, from the top of the nose to the parting of the hair. This is always called a *face*. Another measurement of the same length, from the parting of the hair to the crown of the head, completes the head, which is computed to be one-eighth of the figure measured as before. In practice the last measurement is generally found to be a little smaller than the rest. From this it will be seen that even

\* Read before the South London Photographic Society.

in the case of a bald person, or where the head is covered, there need be no difficulty in finding the top of the face; it is only necessary to take a point the length of the nose above the nose itself. As Mr. Hubbard has correctly stated, the measurement by faces, which is held to be the more correct, is generally adopted by sculptors, who, as they more frequently represent the nude figure, are obliged to be very particular in their proportions. The other, although less exact, is found more handy by painters, and sufficiently true for their purposes. Thus the shoulders are said to be two heads across. The body, including the head and the legs, are each four heads in length. The head and chest to a level with the nipple are equal in length to the remainder of the body—that is, two heads. The legs, again, are divided into two equal parts at the patella, or knee-pan. It will be seen from this that the eight-inch face will give a head about ten inches. Now, whether we multiply the first by ten or the latter by eight, the result is the same, namely, six feet eight inches as the height of the figure. It strikes me the recruiting sergeant would pronounce this rather above the average of humanity. I will not weary you with any more of these details. Should any of you wish to pursue the subject further, I cannot do better than refer you to Flaxman's Lectures on Sculpture, to Bonomi's work on the proportions of the human figure, or to the numerous observations on the subject to be found in Leonardo da Vinci's Treatise on Painting.

The enlarging processes have certainly made much progress within the last year or two. No doubt something of this is due to the improved quality of the negatives themselves, especially where they are prepared on purpose for enlarging. Still more, however, I believe, is owing to the superior beauty and fitness of the transparencies; for the old process of producing the enlarged prints from the negative direct may now be considered as obsolete.

Mr. Croughton has given us much valuable information on the treatment both of the transparency and the enlarged negative. As this information was of a practical character, and has since been supplemented by more useful details, I think we are much indebted to him; as, indeed, we must be to all who freely impart the knowledge they have gained at the price of much toil or experiment. Much of this information was not new to me, as I have for some time been working one of the so-called secret processes very closely corresponding to it. Mr. Edwards reserves his information on this subject until we have gone through the process of hauding him five guineas each. I am afraid this little preliminary will prove an obstacle to most of us, notwithstanding the recommendation of our enterprising friend Mr. Tully, who has himself gone through the ordeal. It is, I believe, no secret that Mr. Edwards's plan depends for its success principally upon the transparency being made upon a structureless film of albumen. A similar film, I am happy to state, is about to be placed within the reach of every photographer by my friend Mr. Kennett, whose sensitized gelatine pellicle appears to me to fulfil all the conditions required. I have seen plates both coated and developed by the new plan, and can truly say that I have never seen anything more simple, or producing more pleasing results—at any rate, in the hands of the inventor. The pellicle, as it is called, will be supplied at such a rate that two dozen half-plates may be prepared by the photographer at a cost of one shilling. Surely this is a step in the right direction.

As most people do, I have put off the consideration of my troubles as long as possible; but the story must be told. It was about the commencement of September last, on my return from a trip in the country, that the idea first occurred to me that I would compete with the rest in the smaller series of the Crawshay prizes—the 4½ inch faces upon 15 by 12 plates. Having a 5 D Dallmeyer lens, and a camera 15 inches square, opening to about 3 feet 9 inches, I thought myself fully equipped for the purpose. I was soon undeceived, how-

ever, for the lens proved too small, and the camera just a thought too short. I had, however, imbibed the idea, and was not easily daunted. I made up my mind to go in for the smaller set; perhaps even for the larger. "Ce n'est que le premier pas qui coûte," said Napoleon, who is generally allowed to have shown great skill in taking off life-sized heads by a process very direct indeed. I soon borrowed a 7 D from a friend, and my assistant knocked up a box about 18 inches deep, which we fixed to the front of the camera, thus making the latter more than 5 feet long. The next thing wanted was a bath. I consulted the catalogues of the dealers, but it was evident that nothing suitable was to be had under a bank note. I had not yet entered into the spirit of the thing, so I hesitated. I remembered, however, to have read in the journals a description of a wooden bath coated with pitch. Just the thing! I got a carpenter to make me a large bath of ash, with a hinged lid, and a bar fixed horizontally near the top. Having cut a suitable hole in the top of the table made with a stand, this bar not only prevented the bath slipping through, but enabled me to rock it very easily. The bath was made up according to the formula of Elbert Anderson. The next thing wanted was a dipper. I have a decided objection to ebonite in any shape. I was told glass dippers were not made of sufficient length; still I bought the longest I could get. It proved too short by several inches, so we made up the difference with string, and pulled it up by a loop. The dipper, being slight and brittle, soon broke at the bottom. Here was a fix. "Who loves a garden loves a greenhouse too," said Darwin. Happy thought!—a wooden bath should have a wooden dipper. Looking about, I spied an old rose-wood T-square that had been knocking about for many years. Just the thing; with a little cutting it held the plate capitally. The weight of the plate carried this new-fashioned dipper to the bottom of the bath, but, being very buoyant, we had to lift it carefully, as it had a tendency to jump out. Only one thing now remained—the camera-stand. All our efforts to use or improve those I had were unavailing; they proved too short and too unsteady. A deal table with a wooden bar to raise the back of the camera answered the purpose very well.

(To be continued.)

## MY EXPERIENCE IN TAKING DIRECT LARGE HEADS.

BY H. GARRETT COCKING.\*

HAVING heard from my father (the secretary of this society) that Mr. Aldridge was going to read a paper with the title of "My Troubles in Taking Direct Large Heads," I thought I would give a few remarks on the way I got my large heads for the recent Crawshay competition.

The idea did not occur to me till a few days before the date on which all pictures had to be sent in; therefore you will see that my time was very short—the more so as I was the only part of the apparatus that I had. But through the kindness of one of the members of this society that difficulty was soon overcome. Not having a dipping-bath for so large a plate, I was forced to use a flat dish; therefore now, having got apparatus and bath ready, I set to work—with what success you can judge from the two specimens I have brought down with me.

In my first trial, I placed my sitter in the centre of the glass house (which is about twelve feet wide), and found that the exposure was very long—in fact, about three minutes. I saw at once that that was too long; so, trying another, I placed the sitter this time close to the glass (side light), and then the exposure was shorter a great deal—in fact, less than one minute, and that I call very short considering the time of year these negatives were taken, and the very foggy weather we had at the time for ending pictures to the exhibition.

\* Read before the South London Photographic Society

The large head of a gentleman was only taken the day before the time for sending them in, at a little after nine in the morning. The exposure for that was about forty-five seconds, which, in the summer, on a fine day, would be less than thirty seconds. That exposure cannot certainly be called long, especially with a lens (Ross's  $4\frac{1}{2}$  diameter) that was not made for that sized head; and if you are going to say, as I read in one of the journals the other day, that "we must have enlargements because of the expense of the lens for the direct heads," I think the question of expense has nothing to do with the question which are the best—enlargements or direct heads.

I also find in these large heads that if the blinds for shading are kept a long way off the sitter, the shading is very easy indeed, for the face, to a certain extent, will give shading, and more violent shadows can be thrown on these heads than on the smaller size, and, therefore, more powerful effects can be obtained.

I think that enlargements for children are useful, as they cannot possibly sit the time required for the direct large head; but for adults direct pictures are far the best. Take, for instance, the large pictures at the recent exhibition on twenty by sixteen plates, full length: what enlargements can come up to them for tone or natural expression?—for I contend that in enlargements there is a want of life-like expression. Or, again, take the half-figures on same sized plates: who would wish for better? And if the public want larger than those, I say that photography ought to go out of the field, and leave the artist on canvas with his brush to paint the large heads.

Enlargements are all very well for landscapes, where there is no expression wanted, but merely light and shade; then they are very useful indeed, as the time of exposure is a great point.

I think the slight want of sharpness that now occurs in the large direct heads (through the want of a large lens) is not so much an objection, as the intense sharpness all over enlargements, which is what the enlargers are now striving for. There are a good many parts of the face that are better for being slightly out of focus. Photographers must, sooner or later, come to prefer large direct heads to enlargements; and for my part, when the apparatus and chemicals for taking them have been improved, I can see no difficulty in doing them; and even now, in my opinion, there is something about a direct large head—perhaps the expression "life-like" best expresses it—that is far preferable to an enlargement, and I hope that in this year's competition a good many more photographers will think so too; therefore, more competitors, and, I hope, greater improvements.

#### AMERICAN CORRESPONDENCE.\*

*Ventilation.*—My experience with English dark closets is, that they are even more poorly ventilated than ours, so I trust a few thoughts, as follows, from Mr. R. J. Chute, one of our most practical men, may serve your readers:—

"As we all know, the vapour from ether is heavier than the atmosphere, and is therefore not so easily carried off by the ordinary means of ventilation. It falls and combines with the atmosphere in the lower part of the room, so that the operator is continually moving in and breathing a combination of elements not very well calculated to promote a healthy condition in an organism so delicate as the human lungs.

"Now, the important consideration in reference to this matter is to devise some means of ventilation that shall carry off the fumes that fall as well as those that rise. I have long had in mind a plan which I intended to try whenever I should have occasion to fit up a dark room, but as there seems no immediate prospect of my putting it into operation, I will make the suggestions in hopes they may prove of benefit to somebody else.

"I should construct a ventilator, if convenient, on the side of the room and near the place where the plates are to be coated with collodion, but I would make this a secondary consideration if I could run it up against a chimney flue or stove funnel, as the

important point would be to warm the ventilator, and thus secure an upward current; or else let the outside arrangement be such as to secure the desired upward movement. If not put in when the room is built, let it be put up against the wall. It need not project more than two and a-half or three inches from the wall, but let it be eighteen inches or two feet wide, making an opening something the shape of the inside of a large bath-holder, running up the wall. It should come down to within about three feet of the floor, and be open at the bottom. With a current of air drawing into this the collodion vapour, as it falls from the plate, would be immediately carried away. In order to supply the room with fresh air, I should have a perforated wooden or tin pipe run around near the top of the room, and connect either with another room where it would get a good supply, or else run it outside. This could be regulated by a damper, so as to admit as much or as little fresh air as desirable. A small ventilator, in or near the top of the room, to carry off the hot air in summer, would complete the arrangement, and, I believe, would give a well ventilated, healthy dark-room.

"The principle of the arrangement is to ventilate from the bottom of the room, and, while carrying off the chemical vapours that accumulate, avoid dust that might be carried up where the ventilator is exclusively at the top. If it be not practicable to carry the ventilator up near a chimney or funnel—and this would only be of advantage in cold weather—I would suggest that it be carried out of the highest part of the room, so that it might be warmed as much as possible by the heat that rises in the apartment. In order to secure an upward current of air, or prevent it from blowing down, as it will do sometimes, a damper or valve, something on the principle of a valve in a pump, might be placed in the upper part of the ventilator, which should be either square or round, so hung that the slightest current upward would open it, while a downward movement would close it."

#### A SIMPLE METHOD FOR PHOTOGRAPHING MICROSCOPIC OBJECTS.

MR. THOMAS H. PINELL gives the following method in our excellent contemporary, the *English Mechanic*:—

"If a piece of ground glass be held several inches above an upright microscope, the object beneath will be seen upon the glass; the size being dependent on the distance that the glass is held above the eye-piece. It is clear, then, that if a sensitised plate be substituted for the ground glass, and protected from all light except that coming up the tube of the microscope, a negative can easily be taken, if the light be sufficiently powerful to affect the silver film. The following method of so taking a negative is very simple and inexpensive, requires little apparatus, and the use of but one room.

A, the camera; B, the camera support; C, eyepiece of microscope; D, body of microscope; B, slide rests; dotted line shows the slide in position.

"For a camera, a cardboard box should be used (*e.g.*, a strong 'seidlitz powder' box), a circular hole being cut in its bottom  $2\frac{3}{4}$  inches in diameter; and two slips of card pasted along both ends to prevent the slide from being rubbed, and to hold it firmly in its place. To support the camera, two or three cardboard boxes should be fastened

together, and holes punched through them to admit the passage of light; the topmost corresponding in size to the camera, beneath a smaller one, and under this a yet smaller, which is best circular in shape; the three, when fastened together, being of such a height that the slide is supported from six to eight inches above the eyepiece. (The camera can, of course, be supported in any other way, but this way is preferable, as lightness of construction is needful.) Lastly, cut a hole in the bottom of the lowest box, so that the eyepiece, when the cap is removed, may fit tightly within it. The negative should be taken at night, or in a dark room; the *modus operandi* is shortly as follows.

"Place the microscope upright, insert and focus your object, using a candle as an illuminating agent, and to obtain a powerful light, place a condenser between the microscope and candle, so that the light may be condensed upon the concave mirror. Next adjust the camera-support and camera, placing a piece of ground glass in the rest intended for the sensitised plate; upon this the object is seen, and must be carefully focussed. Take off the camera, remove the ground glass, and substitute a sensitised plate; replace the camera, then burn in the candle about an inch of magnesium wire. Remove the camera, take out the plate, develop, and sensitise in the usual way. The light from the candle should be rendered mono-chromatic by sprinkling on the wick a few grains of salt."

### ON DURABLE SENSITIVE PAPER.

BY J. M. TURNBULL.\*

IN saying a few words in opening the discussion on this subject, it will not be out of place to begin by stating the importance of having a prepared sensitive paper which will keep for some time. There are a great number of photographers to whom such a paper will be useful. To photographers who print in large quantities, and whose prints are toned regularly every night, such a paper may not be of much use; but to parties who have only a few prints, and who only print at times, a paper that will keep for some time is a great advantage. When such a person has a few negatives ready for printing, or when a good day for printing comes, it puts off a good deal of time to prepare paper, and sometimes in the winter the best part of the light is gone before that can be done. It is also very useful, when the prints are not done enough at night, to lay them aside till the next day, or till some other time when it may be convenient to print them.

About the beginning of 1872, I devoted a good deal of time and trouble in preparing paper that would keep sensitive for a time, and on the 3rd of May in that year I published in the PHOTOGRAPHIC NEWS a formula for preparing paper to keep. The paper which I prepared at that time I was hardly satisfied with, as it scarcely gave prints equal to that by freshly-prepared paper, though it possessed excellent keeping qualities. Some that I kept for more than twelve months was still white enough to give good results.

You will here allow me to say that I should not be satisfied with any paper, however prepared, which did not give prints equal to those on the best freshly-prepared paper.

There are three qualities which a perfect keeping paper should possess. In the first place it should keep well for some time (say from four to six months); secondly, it should tone easily, and give a good tone; thirdly (though it should come in the first place), it should give results equal to what I may call a standard—that of freshly prepared paper. I am afraid, however, that these three qualities are not so easily combined, and that the paper which will possess them all, is still a thing to be found. It is perfectly easy to prepare a paper that will have the first-mentioned quality—that of keeping. I here show you a couple of prints on paper prepared twenty-two months ago in which the white part is scarcely at all yellow;

but you may see at once that it does not give a good vigorous print—in short, though it has the first, it lacks the other qualities.

I may lay it down as the result of my experience, that the longer the time albumenized paper is prepared to keep, the less satisfactory will be the results. I have also proved this from samples I have tried of papers prepared commercially, but whose method of preparation is still a secret. One sample of paper which I procured kept very well for upwards of three months, but, after printing and putting in water before toning, turned (evidently from something in its preparation) very disagreeably transparent, as if saturated with something of a waxy or oily nature, which it never entirely lost, even when dry and mounted; it also toned very slowly. The difference was most apparent when toned beside other prints or freshly-prepared paper. It also had, as I have already said, when mounted, a sort of transparent look, and a sort of woolly appearance; in short, it was not up to what I have called my standard, and therefore did not please me.

I had also another sample of paper, prepared commercially. It gave very good prints, of which you have a sample; it also toned easily along with prints on fresh paper, but is somewhat deficient in keeping qualities. I have here a piece of the paper, about seven weeks from the maker, which, although it has been carefully kept in a tin case, is quite discoloured—too much so to give good prints.

Here is a print by a paper with which I am greatly in love—I mean the collodio-chloride. Prints by this paper have a singular beauty, and a rendering of all the finer half-tints and delicate details in a negative—a sharpness and a softness combined, if I might so speak—which it is improbable can be given by an albumenized paper. But though I thus praise the paper, it has thus its defect: whenever it touches the water to wash or tone it, it has an inherent tendency to roll or curl up, which does not leave it till finally on the mounting-board. There is also a difficulty with the toning: if toned to anything like the colour that an albumenized print should have, it gives a poor, bleached, blue-looking tint, nothing like what it was when it left the frame. The toning can be got over by under-toning the print to the look, as when fixed the print comes a great deal in the tone. Could a paper of this kind be perfected, to give as little trouble as albumenized paper, I have no doubt that it would be the printing process of the future for small work, such as cards. The paper has the merit of keeping good for years. The samples which I now show are between two and three years prepared, and are very slightly coloured. Prints on this paper have also a permanent character, and have also, as I have already said, a beauty which we can never hope for in prints on albumenized paper, or, in fact, by any paper or process.

I will now give, in a few words, the method by which I prepare albumenized paper to keep for a few weeks. Paper so prepared can also be made to keep for twelve months, but I do not recommend that, as it is at the expense of the toning and finished result.

I do not think paper by this method should be prepared to keep more than two to three months. The paper is first floated on the usual silver bath of from forty to sixty grains, and hung up to dry; when nearly dry, but not dry enough to curl up, it is floated on a bath of citric acid five grains, water one ounce. It must not lie any time on this bath—just so long, and no longer, than that the paper may lie flat, when it is again hung up to dry. Such paper will keep white for some weeks. Should the paper be wanted to keep longer, it may be left a little longer on the bath, or the citric acid may be increased to ten or fifteen grains, when the paper will keep longer, but not give such good results. Paper floated on the five-grain solution tones as readily as, and gives as good finished prints, as the ordinary paper. Here are prints by it, both toned and untoned, from which the members can form their own opinions.

## THE PHOTOGRAPHIC SOCIETY OF LONDON.

WE have been inundated with letters during the past week relating to the crisis in the affairs of the Photographic Society of London. Some of these letters consist of angry comments on, and protests against, the proceedings at the meeting of Tuesday week. Little purpose could be served by the publication of such letters now, and we merely give insertion to two or three in which moderate counsels prevail. Other correspondents ask for advice and information as to action in an emergency for which few precedents exist. At present we can simply reiterate the advice given in our last, and urge our readers to do nothing rashly. For the moment little more can be done than to wait and watch the issue of events. How far the legality of the proceedings at the two meetings can be successfully questioned we are unable with certainty to state. A correspondent writes to state that all the proceedings were illegal. The rules are silent as to the mode of voting in the case of a motion like that brought before the special meeting; but as the ballot is prescribed in other cases, it would not be unnatural to suppose it applicable in such a case. Had the ballot been employed in taking the votes, possibly—or, indeed, probably—some of those acting under the instructions of the requisitionists, who hesitated to secede from their leaders openly, would have voted with the council. One gentleman who, not being a member, signed the requisition, is also said to have voted; but whether these things invalidate the vote we are unable at present to say. The vote for the council was unquestionably illegal in spirit; but whether it will be construed so in the letter, is more doubtful. The mode of election is distinctly prescribed as by ballot, the very essence of which is secret voting. Here a large number of persons met together and were pledged to vote for certain names indicated to them; and as very few but those persons were left in the meeting when the voting took place, the ballot, as the ballot, was practically a farce.

Amongst the letters we have received, are some earnestly urging us to use any influence we can to secure the restoration, at least for the present, of the council and officers who have resigned. That is a question upon which we can say very little. Whether these officers could be induced under any solicitation to again accept office we cannot tell. So far as the good of the society is concerned, the advice of "An Independent Member" appears to be prudent. He is desirous of seeing the late officers under-

take office until the rules are revised, and a new council and officers can be elected under the revised provisions which shall be made. He appears to hold the view once enounced by President Lincoln, under somewhat analogous circumstances, to the effect that it "was not wise to swap horses whilst crossing a stream." If the late officers could be induced to resume duty until new rules were framed, accepted, and confirmed, and then, resigning in a body, such of them as felt disposed presenting themselves for re-election under the new regime, it would doubtless be for the benefit of the society. But as such a result could only be obtained by unanimity in a meeting asking them, and unanimity amongst themselves in accepting such an invitation, the issue is scarcely likely to be secured.

Col. Wortley proposes a bold project, and one well deserving of serious consideration. Failing the rehabilitation of the Photographic Society of London, which many seem to think must dwindle into a purely local society, he suggests that a Photographic Society of Great Britain shall be at once established. A large number of distinguished photographers have been by the recent proceedings severed from the old society, many more residing in all parts of the country have no sympathy with the agents in this agitation, and if the project were well headed, a large following might be secured without difficulty, and the result might be a National Society, with wider aims than that which has just been so rudely shaken. With the older and more distinguished members of the society, much of its prestige would be transferred to the new society to which they would give adhesion. The project has much that is attractive; but we must confess, that until we see a restoration of the honoured position of the old society placed beyond hope, we should be sorry to see any steps taken which would precipitate its declension into the merely local position prophesied for it by some. We can therefore at present only reiterate our advice, "watch and wait."

## PHOTOGRAPHIC BAS-RELIEF.

WE have recently had our attention called to a pretty novelty in portraiture, which, like many ingenious novelties, owes its origin to France. The new portrait is a bas-relief on a photographic basis, or rather a photograph on a basis modelled in low relief. The examples we have seen are all of cabinet size, and consist of large bust portraits, both in profile, three-quarter, and full face, the first-named being, we think, most suitable and most effective. How the bas-relief is produced, whether dependant upon some ingenious process, or upon the personal skill of a modeller, we are unable to state. All that is necessary to the result is, we understand, that a plain paper print shall be forwarded to the artist, and this plain paper print is modelled into the due relief, the back being filled up with some plastic material. Some of our readers may be familiar with a similar kind of portrait in relief modelled in wax, and tinted in the colours of life. These photo-bas-reliefs are similar, but, instead of being coloured, they are in the simple black and white of the photograph, which is, in our estimation, much more severely artistic and satisfactory than the tinted wax. A good photograph, perfectly indicating the modelling in the original, must, it is manifest, be a necessary aid in the production of these plastic portraits. In the examples we have seen, every undulation in the contour of features, bosom, hair, and drapery is admirably rendered, and the result is singularly pleasing. The project for an English agency is scarcely complete at the time we write; but we hope shortly to be able to announce conditions which will enable English photographers to secure such portraits for their sitters on satisfactory terms, and without further trouble than is involved in sending a plain paper print—we should recommend a carbon print—to the artist's agent, from whom, in a few days, it may be again received, a charming portrait in bas-relief.

### PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

WE have pleasure in announcing that the Photographic Department at the forthcoming International Exhibition of this year has promise of greater success than has distinguished the exhibitions of the last two or three years. The gallery set aside for photographs is in a better position than at preceding exhibitions, a room in the Albert Hall, on the level of the Conservatory, and forming a direct thoroughfare in the Exhibition, having been devoted to the reception and display of the photographic contributions of the year. The committee having charge of this department have resolved to invite the contribution of examples of the life-size and other large portraits produced for the Crawshay competition, and we hope to see not only some of the specimens exhibited in that competition, but also some of those which, from various causes, did not find their way into the Gallery in Pall Mall. To afford facilities for dealing with these additional contributions, her Majesty's Commissioners have resolved to extend the time for the reception of photographs to the 15th of March, and we hope that these extended facilities will afford opportunity, for those of our readers who have not already made arrangements, to send in some of their best pictures. The committee in whose charge the photographic department has been placed by her Majesty's Commissioners are Dr. Diamond, Mr. R. Thompson, Captain Abney, and Mr. Wharton Simpson.

### FRENCH CORRESPONDENCE.

AS I have already stated in my last letter, the *tour de main* proposed by M. Melchion has received, after trial, a most enthusiastic reception. Following the example of M. Franck de Villecholle and M. Liebert, many photographers have exclusively adopted this system of operating, which consists in allowing the light to penetrate into the camera for an instant, and act upon the sensitive plate, before the actual exposure takes place. This plan of manipulating secures a reduction in the period of exposure by at least one-third. M. Franck de Villecholle has essayed whether a similar plan could not be adopted for producing prints upon paper, and this is the method he pursues:—Before placing in the printing frame the sensitive sheet of albumenized paper, he exposes it to the action of daylight for a few moments, just time enough to give it a faint and scarcely perceptible tint, and immediately afterwards he proceeds to print. His first essay was with a very hard negative, which had never given good half-tones, and to his great astonishment he obtained, in a much briefer period than was usual, an excellent picture, with every gradation of tint, such as only a good cliché would yield under the most favourable circumstances. In rendering an account of these experiments, M. Franck stated that every day he made use of this modified printing method, whether for the purpose of accelerating the printing off of copies, or for producing better pictures from hard negatives.

The occurrence of spots upon positive prints, and especially upon albumenized pictures, formed the subject of discussion at the last meeting of the French Photographic Society, held on the 6th inst. From what was said on that occasion, the unanimous conclusion arrived at was that it is absolutely necessary to prevent the piling of prints one upon the other before they are perfectly dry, and to take precautions against the action of damp. M. Franck narrated a circumstance regarding one of his friends who could never obtain his prints free from these distressing defects. M. Franck sent for some of his pictures and cardboards, and mounted the prints on his own premises, when it was found that there was then nothing to complain of in the finished picture. The cause of the defects was, therefore, shown to be on the premises of the photographer himself, and on enquiry it was discovered that his studio

was paved with tiles, which, in a fervour for cleanliness, were washed very often. On the advice of M. Franck the frequent scrubbing with water was discontinued, and then no more spots upon the albumenized paper were observable. It was therefore to dampness that might be attributed these blemishes, which were probably nothing more than fungi, always liable to be produced in a moist atmosphere.

At the same meeting M. Derozy exhibited to the members of the society a new applanatic lens, which he has just constructed, and which is a rectilinear instrument with much depth of focus and width of angle. It also gives very uniform illumination, so M. Derozy assured the members, together with a high degree of rapidity. Several pictures were shown which had been obtained by the aid of this novel instrument, and which were of a most remarkable character. I allude, among others, to a group of one hundred figures, all of which are well rendered, notwithstanding the different planes and the wide angle embraced in the picture.

A Marseilles photographer, M. Joubert, has sought to remedy the lack of sharpness which is often observed in clichés, despite the amount of care taken in focussing. He attributes the defect to the difference in thickness which exists between the sensitive plate and the ground glass plate upon which the picture has been focussed, and he obviates the inconvenience by employing a moveable frame, disposed in the following manner:—The focussing screen is removed from its frame, as likewise the beading which keeps it in its place, and into the dark slide is put a frame one centimetre in thickness, capable of being easily moved. Above and below, outside the frame, traverse pieces are applied, also one centimetre in thickness, against which are pressed two strong springs. Upon these springs is placed the movable frame above mentioned, in which is fixed the ground glass. Finally, at the four corners of the frame are fixed four moveable screws, in such a way that the ground glass may be pressed backwards and forwards at will. Every day before commencing work the plates destined to be employed are examined to see if they take the place exactly of the ground glass, and according to the greater or less difference there is between the two, so the moveable screws are turned one way or the other. This very simple verification may be made by means of a rule, or scale, having the millimetres marked upon it.

If I am not wrong, there has existed in England for some time a Photographers' Benevolent Society. A similar institution has just been established in Paris among photographic employés. It is with us a very useful organization, and one which merits every encouragement. Founded in July, 1872, this society has passed through a precarious existence before it has taken a definite standing; at the present moment, however, its establishment is assured, for it already numbers 150 members, and possesses a social fund more than ample to supply its wants. In exchange for a subscription of two francs a month, every one of the members has the right, when he is ill, to a daily allowance of one franc and a-half during the first thirty days of his illness, and two francs for the sixty days following. Besides this he receives medical attendance gratuitously, as likewise medical comforts. When he dies, the society discharges the funeral expenses, and gives a donation of one hundred francs either to the widow, or to the children if not of age. The society, moreover, takes under its wings the business prospects of the members, obtaining them situations, and so forth; and, to facilitate matters, has a register of vacancies, and assistants out of work, that may be readily referred to. This constitutes an assurance to the assistants of regular work, and a guarantee to employers; for connection with the society is naturally regarded a certificate of honour. The body of photographers generally cannot but gain by this new association, which, in Paris, may be

placed beside the Photographic Society and the Syndic Chamber of Photography.

*A propos* of useful applications of photography, there is a banking house in Paris which exacts from every one of its employés a photographic portrait. These pictures are all kept together, not to form an art collection so much as to provide against unforeseen occurrences which from time to time take place, unfortunately—such as the disappearance of one of the gentlemen from the office after effecting a temporary loan or securing a stray pocket-book containing a few notes of value. By this precaution the police could at once be provided with an authentic representation of the guilty one, thus rendering pursuit and capture a comparatively easy matter. The idea is not a new one, for it was sought to do the same in Government offices of all kinds some time ago; but the functionaries of every grade then objected to such a measure as undignified and injurious, and would have nothing of it. Perhaps the question will now be revived.

ERNEST LACAN.

## Correspondence.

### THE CRISIS IN THE PHOTOGRAPHIC SOCIETY.

SIR,—May I call the attention of the members of the Photographic Society to the fact that all the voting at the special meeting and at the annual meeting of Tuesday week was illegal, and possesses no force whatever. According to the rules, the voting must be by ballot. The new rules were carried and the amendment lost by show of hands only, one person to my knowledge—how many more I know not—voting who was not a member of the society. Had the voting been by ballot, I am persuaded the issue would have been different.

The six officers subsequently elected at the annual meeting in guise of ballot were those to whom the requisitionists were openly pledged in their programme. This open pledge, I submit, not only neutralizes, but subverts and destroys, the ballot, and their election is illegal.—Very truly yours,

LEX.

SIR,—In your article on the recent *coup d'état* in the Photographic Society of London, you urge the members who may feel tempted to retire in disgust, to do nothing rashly, as the resolutions passed at the last meeting were not yet law, and possibly might never be; but you do not explain what remedies are available, or what steps can be taken, in the present state of disorganization.

I can quite see, sir, that the complaint in your last of too much of your valuable space being occupied by the squabbles of a local clique was not without reason, and if you will give me space for one or two suggestions I will be very brief. The Photographic Society, which has had a national character, is threatened, if not with dissolution, with becoming a purely local society, and I think it is worth an effort from the three hundred members, or nearly, who have not taken part in the conspiracy, which consists of an insignificant proportion of the members, to avert the catastrophe.

At present there are only the six officers elected on Tuesday evening, and the election of these is so doubtfully legal that Col. Stuart Wortley, I understand, threatened them with a *mandamus* if they spent one penny of the funds of the society. The resolutions passed at the special meeting do not, I understand, become law until confirmed at a future meeting. If the independent members of the society are sufficiently interested in the matter it would not be difficult at the next meeting to refuse confirmation of these resolutions.

I believe that a great many of the requisitionists are not well pleased at the issue as it stands. Would it not be possible for the moderate men of all views to join in a request that the president and council would resume duty for the present year, during which a committee less one-sided in its composition than that already appointed might revise the laws and bring them before a special meeting for approval, care being taken to give the country members a voice. Then, with new rules and more complete representation of the whole society, all officers might resign at the end of the year, and a complete new election under the new rules take place. The council could then retire with as much honour as they can now, but with less injury to the society.—I am, sir, very respectfully yours,

AN INDEPENDENT MEMBER.

DEAR SIR,—There are cases where defeat is more honourable than temporary victory, and I feel sure that many of the members who voted against the president and council at the special meeting would not have done so had they not been caught by guile, and foolishly pledged their word how they would act before any meeting of the members had taken place, or explanation on the other side made. By their united and ill-advised action they caused a serious and lamentable disruption, and yet style themselves reformers. They also got their leader (Mr. Jabez Hughes) to speak in favour of open and free voting, and then at once proceeded to a ballot, which was a complete farce, as some thirty members had arranged whom to vote for, and the six elected were (with, perhaps, one exception) all from amongst themselves,\* clearly proving that all was pre-arranged, and there was nothing free about it. Now, sir, I believe it is the unanimous desire of the members that everything should be above-board, and as we have had enough of secret combinations trying to undermine a useful and successful society, I trust all this will at once be put an end to; and let the members at the next meeting form themselves into committee to revise the laws, inviting country members to send up suggestions which shall be read from the chair and duly considered. It is to be hoped that all parties and cliques will at once cease to exist, and all amicably combine for the good of the society and the advancement of the art. Let us try our best to reconcile all, make a good code of laws, and then go to work in earnest.—Yours truly,

GEORGE HOOPER.

63, Canonbury Park, South, N.

DEAR SIR,—Whatever may be the result of the present movement for reform in our Parent Society, I trust that the new council will set an example by putting themselves, at all exhibitions where awards are made, as the French do—*hors concours*. This would at once put an end to the suggestions that have been made of members of council having, through jurors composed of a portion of their body, awarded each other medals. I feel sure that no recipient of such awards could, under the circumstances, feel that any *real honour* had been conferred on him. Let it never again be said that out of ten medals, agreed to be awarded at one of our annual exhibitions, six of these were awarded to members of council, one not competed for, and the remaining three bestowed on outsiders.

I would also suggest another point; that is, that the Journal of the society should become something more than a mere record of the society's proceedings, and that the council and members should unite, and, by occasional contributions, make it something more than what it has been.

WALTER WOODBURY.

Greenhithe, Feb. 16th.

[It is, perhaps, a little premature to discuss arrangements for the distribution of medals which may never be offered, and, at any rate, could not come under consideration for many months. But there are some slight inaccuracies in our correspondent's letter. The council of a society do not in France, or anywhere else, that we ever heard of, place themselves *hors concours* in exhibitions. The jurors generally do so place themselves in this country, but in France even jurors are not always placed *hors concours*, although it is clear that they ought to be. Whatever council may be in office, it would be an absurd anomaly and great injustice to prohibit their competition for medals. The council of a society should consist of its most distinguished members, and its most distinguished members are those who most naturally win, and most justly receive, medals. Our correspondent is also inaccurate in one or two other points. There were thirteen, not ten, medals placed at the disposal of the jury; and five of them, not six, were given to the productions of members of council. The Journal question is scarcely one for discussion here; but we may remark that its reduction to its present proportions was due solely to the action of some of the gentlemen with whom Mr. Woodbury is associated—their sole aim being an honest desire for economy. The question of its wisdom they will doubtless be able to explain to a new council, when it is formed.—ED.]

### A PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

SIR,—I find myself unable to accept the nomination to serve on the committee for altering the laws of the Photographic Society, and have written to Mr. Jabez Hughes to that effect. I should like, as an independent member of the London Photographic Society, to be allowed to make a few remarks in your columns on the somewhat unfortunate state of affairs in which the society now is.

\*—And three of these belong to the same commercial firm.

I much regret (and I think that regret is shared by some of the requisitionists themselves) that some attempt was not made to induce the president and council to withdraw their resignations. I did my best at the meeting to favour such a course, but, unfortunately, without effect, and I fear that the future of the society will suffer from the present state of affairs. By the resignation of the president and council the society loses the services of those men who are acknowledged to occupy the foremost positions in photography; and I do not see how the places of such men as Mr. Glaisher, Sir C. Whatstone, Lord Lindsay, Professor Stokes, and Mr. Spiller, among scientific men; and of Mr. Francis Bedford, Mr. V. Blanchard, Mr. W. England, Mr. H. P. Robinson, Captain Abney, and Mr. Sebastian Davis among practical photographers, are to be filled by men of the same calibre from the remaining members of the society. We also lose the services of Mr. Biden Pritchard, the excellent secretary to the Society, and of Mr. G. Wharton Simpson, and of Dr. Diamond, who has been connected with the society from its commencement. Under these circumstances I would venture to suggest that if the services of these gentlemen are withdrawn from the Photographic Society of London, the society will lose much in prestige, and will not in future occupy the same position in the eyes of the photographic world as it has hitherto held.

I fear that under the circumstances none of these members will be induced to return to the council, which I think many of us would feel to be a misfortune, because there are men among them whose absence from the society's council will be a serious loss to it; and I therefore suggest a medium course by which photography may yet have the benefit of their services—a society established on a firmer and yet wider basis than is the case with the present Photographic Society of London.

I believe this to be an excellent time to establish a society which shall be called the "Photographic Society of Great Britain," and I believe that such a society would meet with very general support from the great body of photographers. If it were to hold a biennial meeting in one of the large towns of the country, in the same manner as is done by the British Association, great interest would be lent to its work, and the fact of such being a part of its programme would, I think, obtain for it large numbers of subscribers among country photographers. I should hope, and indeed believe, that were such a society now organized, a majority of the gentlemen who have resigned their seats on the council of the London Photographic Society might be induced to give their support to the new one, and we might further hope to have the names of Professor Piazzi Smyth, of Edinburgh; Professor Emerson Reynolds, of Dublin; R. M. Gordon, J. W. Swau, and other eminent men not resident in London, on its council; and Mr. Stillman and Mr. Jabez Hughes, both valuable members of the council of any society, might also be willing to join, the more so as they are pledged not to join the council of the London Society. I venture to hope, too, that our valued friends Dr. Mann, and Mr. P. Le Neve Foster would also give their co-operation, and the elements for the formation of a society of great weight and influence are thus under our hands.

I may also point out that so strong a society could undertake investigations in the various branches of photographic science, could award medals for progress in photography, and could, I believe, be of very great use to the general body of photographers.

Further, I believe that the establishment of such a society would greatly improve the position of photography in general; such a society could watch over its interests with advantage, and it might eventually—and that, possibly, before very long—obtain a charter, and the right to elect fellows, and to have other privileges such as those held by societies of other denominations.

I throw out these suggestions to the public through your columns in the hope that they may be worked into some definite shape. I feel sure, from conversations I have had with many personal friends, that the establishment of such a society would be looked on with great favour, and I think everyone will agree with me that if such a society is to be established, now is the time, and this the opportunity, for it to be done.—I am, sir, yours, &c.,  
H. STUART WORTLEY.

#### PHOTOGRAPHIC BENEVOLENT ASSOCIATION.

DEAR SIR,—In order to bring the existence and claims of the Photographers' Benevolent Association under the notice of all photographers in the country, and to guard the funds against fraud, the rules provide for the appointment of local secretaries in provincial towns.

I shall be pleased to communicate as to terms, duties, &c., with

any gentlemen who will notify their willingness to undertake the office.

All appointments made will be advertised in the NEWS.—I remain,  
W. T. WILKINSON, Secretary.

14, South Street, Bromley, Kent.

#### SHEET GELATINE.

DEAR SIR.—You will remember that in your YEAR-BOOK for 1873 I wrote a short article on the above subject, and some time after (in consequence of the difficulty experienced by some photographers in getting sheet gelatine) I offered to send a few sheets as a sample to any one who would apply to me.

For several weeks I was inundated with applications, and it really took up a considerable portion of my time to attend to them; then came a lull, and I thought the thing had died out. Within the last few days, however, I have had another rush. So, having very little spare time at my disposal, I shall feel obliged if you will kindly insert this letter in the NEWS, in order that those of your readers who think of applying to me may oblige me by favouring one of the manufacturers instead, whose addresses you gave in your last volume.—Yours truly,  
F. A. BRIDGE.

30, Dalston Terrace, Dalston Lane, London, E.

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

#### Report of the Council.

"THE society is again to be congratulated on the continued financial improvement in its affairs inaugurated some years back. The outlay has been carefully watched with an economical spirit, so that no undue expenditure of the funds should take place; and the consequence is that there is again an increase in the assets of the society to be reported. This is a point the importance of which cannot be too highly rated; for, as experience very clearly shows, the financial condition of the society influences in a marked degree the services it renders towards the progress of the art, and the interest which its proceedings awaken among the members; for it cannot be denied that the communications and discussions at the meetings of late years have been more frequent and more fruitful than was the case during the period when the society was oppressed (as some thought, hopelessly) with debt. The annual presentation to members of a picture which worthily represents contemporary photographic art has now been regularly established, thanks to the surplus funds in hand; and Mr. William Bedford's 'Old Devonshire Cottage,' which was the print selected last year for distribution, seems to have met the general approbation of members.

"As regards the proceedings of the society, the papers read during the past session include several of considerable importance. At the last anniversary meeting, twelve months ago, it will be remembered that the Secretary of the Royal Society, Professor G. G. Stokes, M.A., D.C.L., gave a discourse 'On the Principles of the Chemical Correction of Object-Glasses,' thus inaugurating the year with a most valuable contribution to photographic optics. He pointed out the discoveries since the days of Newton which had contributed to make lenses of all kinds what they are at the present day, and then proceeded to explain the laws which govern opticians in putting together their lenses, and the reasons of the particular combinations adopted; and he especially referred to the difficulties experienced in securing an object-glass with the most efficient chemical rays, as compared to one in which the visual rays is the main point to be considered.

"At the March meeting the secretary called the attention of the society to a work by M. Victor Fouqué in a paper entitled 'A Contribution to the Early History of Photography.' He supported his remarks by extracts from the book, which, while it placed beyond a doubt the fact that Nicéphore Niepce had been the first to produce permanent pictures from nature in the camera by means of bitumen of Judea, in 1823, also claimed for him the production of camera pictures upon nitrate of silver paper as far back as 1816. From the published letters of Niepce to his brother, there would seem no reason for doubting his claim thus to be considered the first photographer. It was further pointed out in the communication that the assistance and information which Niepce gave to Daguerre upon the establishment of a partnership between those early investigators were of a very complete nature, and seemed to point most unmistakably to the fact that some of the main ideas

elaborated in the process of Daguerreotype emanated from the earliest of photographers, Nicéphore Niepce.

"A paper 'On the History of some Early Photographs, Uranium Prints, &c.' was read by Mr. John Spiller at the April meeting. The author called to mind that uranium had from time to time been frequently resorted to by photographers in their work; and the production of ferrocyanid of uranium prints, as practised some time ago by Mr. Robert Hunt and M. Niepce de St. Victor, ought not to be lost sight of. The peculiar and pleasant tone of the three pictures was such as to recommend them under certain circumstances; and Mr. Spiller not only explained, but demonstrated the working of the process before the society. On the same occasion, Captain Abney, R.E., criticised, at some length, the chemical theory of the latent image as propounded by Dr. Reynolds. He believed that gentleman to be perfectly correct in his assumption regarding the action of light upon iodide of silver, as to two bonds of iodine being liberated by the same, and being thus free to enter into other combinations, but deemed it a moot question whether the image was formed of sub-iodide of silver by the addition of silver or by the abstraction of iodine. The author rather inclined to the opinion that the sub-iodide was formed in the latter manner, no image being capable of development on iodide of silver without the presence of an iodine absorbent.

"In May a communication relative to two novel methods of carbon printing by M. A. Marion was read. The two processes were termed 'Mariotype by Pressure,' and 'Mariotype by Contact.' The author supported his statements by some excellent illustrations of pigment printing, produced by the methods he described. 'Mariotype by Pressure' consisted in exposing a sheet of bichromated gelatine to the action of light under a cliché, and then transferring it to a bath of weak bichromate solution, and afterwards employing it in a press as a printing block. Instead of being inked, a solution of bichromate of potash and chrome-alum was applied to the surface with a sponge, and then a sheet of carbon tissue pressed down upon its surface. This latter in part absorbed the chrome-alum, where this liquid had permeated the printing-block—viz., in those parts unaltered by light—and after the two surfaces had been in contact for a brief period the tissue was withdrawn, the block again moistened, and the operation repeated. The tissue was then developed, and an image formed by such portions which had been fixed by the chrome-alum refusing to wash away. 'Mariotype by contact' consisted in sensitizing a sheet of gelatinized or transfer paper, printing upon the same with a negative, and then pressing a piece of tissue moistened in bichromate solution upon the gelatine image. The development took place some hours afterwards, when the black pigment was found to adhere to the gelatine image. It is much to be regretted that M. Marion, who was a member of this society, did not live to work out more fully these promising processes, which only represent a small section of the good work he did in aiding the progress of photography. He fell ill within a few weeks of their being made public, and died in the course of the summer. Mr. F. R. Elwell, at the same meeting, contributed some valuable notes on instantaneous photography, for which he has acquired considerable reputation. He detailed his plan of working, and gave the formula of the developer he employed.

"In June Mr. Jabez Hughes read a paper 'On Improvements Needed in Photography, and Remarks on Three Wet Processes.' The author pointed out how very little progress had of late years been made with the wet collodion process; for with but one or two exceptions it still was as when Archer published it more than twenty years ago. Mr. Hughes then went on to discuss the merits of three variations of the wet process, viz., the acid-bath system of Mr. Black, the heavily salted collodion of Mr. Elbert Anderson, and the wet bromide process of Major Russell. Although he had experimented very fully with all three methods, he could not take upon himself to say they would produce ultimate improvements, for it was only after long and patient trial that a trustworthy mode of working could be ensured. He had more hope of improvement resulting from following Mr. Anderson than Mr. Black; and probably when the bromide process had been practised as long as the ordinary bromo-iodized, it would be as thoroughly understood and appreciated. Mr. Hughes concluded by urging photographers to give more attention to original investigation as the best means of ensuring real progress in the practice of photography.

"A paper on Photo-collotype Printing was contributed at the same meeting by Captain Waterhouse, who described the uses to which carbolic and nitric acids might be put in the method, and gave other information of practical value. This paper Captain

Waterhouse supplemented by another at the December meeting, containing additional notes on the subject.

In December also Lieut. Chermiside, R.E., who accompanied Mr. Leigh Smith in his tour in the Arctic seas, gave an account of photographic practice in high latitudes, and narrated several interesting details connected with the manipulations to be performed under very unfavourable circumstances.

"In January Dr. Mann exhibited a large series of photographs illustrating the eruption of Vesuvius of April, 1872, which had been collected by Mr. J. M. Black. Dr. Mann called attention to the perfect manner in which the phenomenon had been recorded by photography during the whole period of the eruption, and how graphically the course taken by the lava over the surrounding country had been depicted. A note on Sepia-toned Prints, by Mr. W. H. Watson, was also read.

"Notwithstanding the difficulties attendant upon holding the annual exhibition in a different *locale*, and at a somewhat earlier date than had been the custom for some years past, the gathering cannot be considered otherwise than as a perfect success, whether regarded in its artistic, financial, or popular aspect. The number of pictures hung exceeded that of the preceding year, while the ambitious dimensions of a large number of them was a matter of universal comment. These bold cartoons and magnificent enlargements were in great measure due to the encouragement given by Mr. Robert Crawshaw, of Cyfarthfa Castle, who has sought to develop a bolder and freer class of work by the offer of a series of handsome money prizes, thus rendering a service to photographic art which must be unhesitatingly recognized. From a financial point of view the result also was a satisfactory one; for notwithstanding the heavy rental of the Gallery in Pall Mall, and the many expenses inherent to moving into new premises, the expenditure was not in excess of the money-takings. So promising, indeed, have been the financial statements of the exhibitions for the past few years that it may be confidently anticipated that, instead of being a burden and expense, as in former times, the exhibition, if well managed, will ultimately become a source of income to the society. It was found impossible to keep a very accurate return of the numbers of visitors to the exhibition, because many friends were admitted accompanied by members; but it may be of interest to know that as many as 1,113 tickets were used by members of the society, admitting in all 2,630 visitors. Besides these, no less than 1,604 persons paid for admission; and therefore, inclusive of members, many of whom paid repeated visits to the gallery, the gross total of visitors could not have fallen short of 5,000. Among the more distinguished who honoured the society with a visit were their Royal Highnesses the Prince and Princess of Wales, who made a careful examination of the pictures. The success of the exhibition was materially assisted by the many important press notices which appeared in most of the daily and weekly newspapers.

"In one branch of photography marked progress may be said to have been made during the past year, viz., in the matter of enlargements. By adopting an improved medium in the preparation of transparent positives, the process of enlarging from the latter has been bettered, as demonstrated by the magnificent productions of Messrs. Spencer, Sawyer, and Bird, Mr. Edwards, and others.

"The preparations made for observing the approaching transit of Venus have led many photographers to turn their attention to consider the best means of applying the process for astronomical purposes. Dr. Krene, of Dresden, has made a microscopical study of different films, and pronounces an opinion that a collodion plate treated with albumen as a preservative is the most stable film that can be depended upon. His research is, however, confined to an examination of the film itself, and does not treat of the influence of various developers. There seems a marked inclination on the part of photographers to use the dry process on the important occasion, without having recourse to any intensifier whatever. The studies of Rutherford, Draper, and Lockyer upon the solar spectrum lead one to infer that photography must necessarily become indispensable in spectrum analysis, for it is only by a combined optical and chemical observation that a true record of results can be secured. Dr. Vogel, of Berlin, has recently confirmed the observations of Sir John Herschel and Mr. Robert Hunt in regard to bromide of silver being sensitive to all rays of the spectrum; and by employing preservatives differently tinted he makes the bromide film possess maximum sensitiveness for different kinds of rays, according to the colour of his sensitive film.

"Among other foreign contributions to photography may be noted an exhaustive treatise on dry plates by Dr. Schnauss, of

Jena, and another by M. de Constant, of Lausanne. M. Léon Vidal's polychromic process, which may be termed rather a mechanical than a photo-chemical method of producing photographs in colours, has created some attention in France and in this country.

"The obituary for the year contains the names of M. A. Marion, to whom allusion has been made, and Mr. E. Bullock, of Leamington."

#### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this society was held in the rooms of the Society of Arts, Adelphi, on Thursday, the 12th inst., Mr. F. HOWARD in the chair.

The minutes of the last meeting having been read and confirmed,

Mr. S. FRY exhibited and explained the working of an apparatus called the "Opal Glass Accelerator," consisting of a circular piece of opal glass fixed in a turned block of mahogany to be affixed on to the front of the lens. Mr. Fry stated that the effect was entirely different to the use of coloured glasses. He exposed the sensitized plate to light passing through the opal glass before exposure to the sitter, and which considerably shortened any subsequent exposure.

Mr. FOXLEE had shown, some time since, a negative which had only required one-half the necessary exposure, having previously been exposed to diffused light.

Several members then gave their experience respecting the transmission of both *white* and *coloured* light, before and after exposure to the object; Mr. Fry's experience being that the preliminary exposure was the best.

Mr. Brooks had found, when working in a tent, that after developing in front of an *orange*-coloured glass, great advantage was gained by continuing development before a *lemon*-coloured glass.

Mr. HOWARD stated that a very good imitation of opal glass might be made by a mixture of collodion and negative varnish poured on a clean plate of glass.

Mr. ALDRIDGE then read a paper entitled "My Troubles in Taking Direct Large Heads" (see p. 86), exhibiting two 15 by 12 prints of heads about five inches.

A very interesting conversation ensued respecting horizontal baths, wooden trays, and length of exposure, &c; after which—

Mr. H. GARRETT COCKING read a paper, "My Experience in Taking Large Direct Heads" (see p. 87), also showing two 15 by 12 prints of heads about five inches.

After a desultory conversation—

The CHAIRMAN remarked that some of the difficulties occurring to Mr. Aldridge arose from using a vertical bath coated with pitch and rosin, which had been avoided by Mr. H. G. Cocking, who had produced clean pictures by at once using an ordinary porcelain horizontal bath.

Votes of thanks were then passed to Messrs. Aldridge and H. G. Cocking for their papers.

It was announced that at the next meeting in March Mr. S. Fry would read a paper "On Studios," illustrated by a working model.

The proceedings then terminated.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE third popular meeting of the season was held in Queen Street Hall, on Wednesday evening, the 11th inst., when Dr. HUNTER delivered an interesting lecture on "India: Its People, Architecture, and Antiquities," illustrated by a large number of fine lantern pictures. The hall, as usual, was crowded in every part.

Dr. JOHN NICOL, in introducing the lecturer, said that it was very gratifying to the members of the society that, although those "popular evenings" had been carried on for so many years, they had not only not fallen off in interest, but, judging from the large audiences and the increasing demand for tickets, were increasing in popularity. As the subjects of exhibition were not confined to the beaten tracks of country, but extended to wherever good photographs could be obtained, it would easily be understood that the committee had often much difficulty in finding lecturers sufficiently acquainted with the subjects. They were, however, peculiarly fortunate to-night in having got Dr. Hunter, who, from a residence of over a quarter of a century in India, and from his intimate connection with art during a larger portion of that time, and also from the fact that he was himself an artist of no mean ability, was eminently fitted for the duties of lecturer on the subject.

Dr. HUNTER began by giving an interesting description of

the social condition of the inhabitants of India, and the influences of missionary and educational efforts on those on whom they had been brought to bear, giving special credit to several maharajas, who, he said, were men of superior attainments, and who could take a place alongside the nobility of our own land, without any cause for being ashamed.

The various styles of architecture were explained and admirably illustrated, and the taste and ability in designs were shown to be such as to put our manufacturers on their mettle if they wished to compete with them in the manufactures in which they excel.

The lecture, which lasted over an hour and a half, was listened to with marked attention, and the large number of illustrations were much admired.

On the motion of Dr. Thompson, a hearty vote of thanks was given to the lecturer.

### Talk in the Studio.

FIXING VANDERWEYDE FINISH.—A correspondent (Mr. Tilley, of Stafford) sends us the following method, which he has found useful in clearing-up and fixing the colour applied in the Vanderweyde and similar processes. He says:—"As soon as the picture is finished and gummed, pour plain collodion over the entire surface, and when dry the picture can be sent through the post without any danger of being rubbed so as to remove any colour. I am aware that collodion has been used over photographic prints before, but not, I think, over the Vanderweyde pictures."

PAPER NEGATIVES.—The same correspondent sends a suggestion in relation to paper negatives. He says:—"Photographers who use paper negatives will find it a great advantage to mount them on glass before printing from, and the retouching can be done with great care, and the prints from them will be sharper, as the negative is then quite flat. Mount them on the glass with warm starch, and let dry."

### To Correspondents.

THE PHOTOGRAPHIC SOCIETY.—We have received a large number of letters in connection with the late proceedings of the Photographic Society, the insertion of which would make a much more serious demand on our space than, in justice to our general readers, we can devote to the subject, as, although the society is a large one, and has done much for the art, its total members do not represent a tithe of our readers. We give three or four letters containing moderate counsels, and we here condense extracts from a few others. "A MEMBER OF THE COUNCIL" calls our attention to the fact that the "letter published in a contemporary on the 23rd ult., as being the letter sent to the council with the second requisition, is a garbled document, a sentence of an insulting character to the council being carefully eliminated from the copy given to the public eye." "A BONA FIDE MEMBER IN THE NORTH" thinks that every photographer in the country is sufficiently indebted to the Photographic Society for its influence in the art to be interested in a discussion affecting its fate, especially at a time when it has been "subjected to a cowardly attack from within its own body," and when its independent members require encouragement and support. He says:—"I am astonished at the audacity of Mr. Hughes and the other requisitionists, who have, as I see by your last issue, brought all the terrors of ruin, anarchy, and revolution into the hitherto peaceful fold of the Photographic Society." After some comments on "the indecency of the allusions to the turf, which might have been expected from a pot boy," he asks, "What could be more insane as a suggestion than that the council, under whose fostering care the society has advanced to a position of successful usefulness never before attained, would put forward three members to serve in a committee who would suggest the least thing which, in their honest opinion, was contrary to its best interest? Why should Mr. Hughes fear that the council would do this?" But he adds, "The improvement of the laws was little to them, so that they might gain a victory, even if they established a reign which should be one of terror." The requisitionists having, he observes, "succeeded, with success comes the responsibility. Their leader is now for a moment the head of the government of the Photographic Society; and holding that position, he must treat with the demands of all members of the society. I do not say he must grant all their demands, but he must treat with them one way or another; and I believe that in this fortunate necessity lies the weak point which will give way when the strain comes, and precipitate the requisitionists to the position they deserve to occupy. They must either grant proxy voting to the country members, or, in letting it alone, they must more clearly than at present define the rights—or rather want of rights—which we at present enjoy, and which I, for one,

have till now been quite content to enjoy. If, then, they grant proxy voting to the country members, I have no hesitation in saying that at the first vote the malcontent ministry will be out-voted beyond all salvation. They will have nearly three hundred against twenty-eight; and some of the twenty-eight will be disgusted with their leaders before then. But if this leader or leaders go for the safer plan (?), and keep the vote to personal attendance, so as to have twenty-eight always at their back, will not the country members follow the lead of their president and council, and resign in a body? I can answer for half a hundred or more who will, and I doubt not the rest, or the bulk of them, will follow suit; for why should they not? They have the best president who could preside over them, and the best council that ever pulled a society through its difficulties, to guide them to future success, honour, and usefulness." The "BONA FIDE MEMBER" concludes by saying:—"I would, however, strongly advise the members generally not on any account to withdraw their names from the list at present, as the proxy vote will give them a better chance of showing Mr. Hughes what they think of him than they can at all express by running away in a hurry; and if the proxy vote is not accorded, they will then have a dignified ground on which to withdraw. But I do not think we shall be driven to this necessity. I do not think that, now that the self-seeking of the requisitionists has become manifest, they will have supporters enough to enable them to carry out much more mischief; and when they fail, and the society has regained its equilibrium, and its members had time to look around them after the storm, I, for one, do not envy the feelings which must inevitably crowd themselves on the minds of those gentlemen who, having held positions in the council of the society themselves for years, and having then found no need for amendment, have, now that their names were not proposed again for election, out of a mean self-love of which I should not have thought them capable, plotted the overthrow of the society itself to its very foundations." "AN ENQUIRER" asks us if the Photographic Society has become a trades union, as he affirms that there are among the six officers just elected five dealers or workers for the trade, and in the committee just elected six similarly engaged; and he then proceeds to enumerate names. We think it undesirable to obtrude into this unhappy agitation more of the personal element than we can help. Some other correspondents on the subject are answered elsewhere.

J. W.—We hope shortly to lay before our readers generally some further details from Mr. Fry of his glass house experiences. A full description of his studio would occupy more space than we can devote to an answer in this column; but we hope to publish the description shortly.

T. HART.—The amount of silver taken up by each sheet of albumenized paper depends upon the proportion of chloride in the albumen solution used in preparing the paper. Suppose chloride of sodium were employed, then each grain of chloride in albumen on the paper would take, in round numbers, three grains of nitrate of silver in forming chloride of silver on the paper, a little more silver would combine with the albumen, and a little more would remain on the paper as free nitrate of silver, and the proportion used in the latter position would depend somewhat on the strength of the nitrate solution. You will see that the proportion of silver used must therefore depend upon circumstances. With many commercial samples of paper it is customary to allow one ounce of nitrate of silver for each quire of paper. Of course ready sensitized paper will cost more than paper sensitized at home; but still, under some circumstances, it is economy to use the ready sensitized paper.

MELBOURNE.—You can obtain lime water of most chemists; or you can make it by getting some clean slaked or unslaked lime, and agitating it with water. Only a very small portion is dissolved, and the lime will last a very long time if you keep adding fresh water.

L. E. D.—We cannot suggest any plan whereby country members can now use any influence in modifying the action of the society. We have not space for the insertion of letters merely of condemnation, which can serve no purpose. We do not know anything of the steps which may be taken in filling up all the vacant offices. Mr. Pritchard, the secretary, has resigned, and, so far as we know, none other is yet appointed.

DEAF-AND-DUMB ARTIST.—We should prefer No. 2 for your purpose. You will see your formulae inserted on another page. Thanks.

A COUNTRY AMATEUR.—You will see that the question of legality is raised on another page. We cannot with certainty say. The issue is, as you remark, both "lamentable and discreditable," but at present we see no remedy.

W. EVANS.—The project you describe is really a lottery, and, as such, is illegal; but whether, in a small matter quite within your own business, the law would interfere, we cannot tell; probably not, but still you would really become amenable to the law if it were put in force.

E. H. SRIGHT.—We hope shortly to publish full particulars. At present we have published all the information in our possession.

P. A. T.—Unfortunately, we have no knowledge of fire offices or their practices; but we should imagine that the majority of them would have no objection to insure a photographer's studio, &c. 2. The usual size of each half of a stereoscopic slide is about three inches square. The precise proportion of the figure in stereoscope portraits is a matter of taste. 3. We do not know anything of the town in question, or its photographic prospects. We should think the best plan would be to spend a few days in the town, looking about and enquiring.

R. E. P., M. D., and L. L.—See article and letters on the subject.

IGNORAMUS.—Your negative arrived in fragments. So far as we can judge from examining them, the stains of which you complain are the well-known matt silver stains, upon which many articles have been written, which you will find in back volumes of the News. Such stains proceed from many causes; but there are two or three most common. One of the most usual causes is the use of a horny collodion upon the surface, of which the silver has a tendency to run in greasy lines, and to dry readily, producing the matt silver stains in question. Another cause is lack of scrupulous cleanliness in the inner frames or corners of the dark slide. Frequently wash out the slide with clean water. Let the plate rest on pieces of clean blotting-paper. Immerse the plate before the film is too thoroughly set or dried. If these remedies fail, look up and read articles on the subject in back volumes.

J. BARRATT.—The varnish has arrived. We shall have pleasure in trying and noticing it shortly. Several Correspondents in our next.

METEOROLOGICAL REPORT FOR JANUARY, 1874.  
BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

1874 January Date.	Morning.	Noon.	Night.	Direction of Wind at 9 a.m.	
1	44°	48°	44	S.	Rain commenced about 4 p.m., with strong wind.
2	44	41	40	N.W.	Fair all day. Gloomy.
3	32	36	36	N.E.	Snow from 9 a.m. to 12.30. Rain early in the morning.
4	36	38	36	S.	Heavy rain, and strong wind at night.
5	35	40	40	—	Fair all day. Bright, clear, and sunny.
6	40	44	40	W.	Fair all day. Gloomy.
7	40	42	40	S.W.	Heavy rain and wind at night.
8	40	40	41	S.	Rain a.m. and p.m.
9	41	45	39	—	Fair all day. Clear.
10	31	40	36	N.E.	Rain early in the morning. Meteor at 11.45 in N.*
11	40	44	42	N.	Heavy rain at night.
12	44	41	39	N.W.	Shower of rain this forenoon.
13	41	44	46	S.W.	Fair all day. Gloomy.
14	46	46	44	S.W.	Fair all day. Gloomy.
15	47	48	40	S.W.	Rain a.m. and p.m.
16	37	38	40	W.	Rain and snow a.m. and p.m. Aurora 10.15.
17	38	41	34	N.	Rain this morning. Gloomy.
18	41	46	42	S.W.	Rain a.m. and p.m. Glimpses of sunshine in the afternoon.
19	41	44	40	W.	Fair all day.
20	45	48	46	W.	Rain a.m. and p.m.
21	44	48	47	S.W.W.	Fair all day. Gloomy.
22	41	46	40	W.	Drizzling rain a.m. and p.m.
23	44	46	42	W.	Drizzling rain this forenoon.
24	41	38	42	S.W.	Heavy hail shower at noon.
25	41	41	42	W.	Rain this afternoon.
26	42	48	40	W.	Hail shower this morning. Rain a.m. and p.m.
27	38	41	40	S.E.	Clear and sunny all day. Drizzling rain at night.
28	46	46	42	N.W.	Drizzling rain this afternoon.
29	41	41	43	S.E.E.	A few drops of rain this afternoon.
30	41	43	40	N.W.	Fair all day.
31	46	48	40	W.	A little rain at night.

The following are taken from the above data:—

	Mornings.	Noons.	Nights.
Maximum temperature during the month	47°	48°	47°
Minimum ditto ditto ditto	32	36	34
Mean ditto ditto ditto	41.1	43.7	40.7

Number of wet days during the month were ...	23
Number of days on which no rain fell ...	9
Number of fair days on which it was gloomy ...	6
Ditto ditto ditto sunny ...	3

The wind from S.W., W., and N.W. prevailed.  
February 13, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### THE PHYSICAL SOCIETY—THE ELECTRIC LIGHT IN PHOTOGRAPHY—TINTING THEATRICAL PORTRAITS—THE CAMERA IN COURTS OF LAW.

*The Physical Society.*—A little while back we announced in these columns that steps were being taken to form a new society, to stand in the position of twin-brother to the Chemical Society, and to which the name of Physical Society was to be given. This body has now been created, having sprung into being upon a very firm basis, apparently. Dr. J. H. Gladstone, who, from the commencement, has shown a very deep interest in the movement, has been chosen the first president, with Prof. W. G. Adams and Prof. G. C. Foster as vice-presidents. The secretaries are Prof. E. Atkinson and Prof. A. W. Reinhold; and among the council are the well-known names of Prof. Guthrie, Mr. Crookes, Prof. Goodeve, and others. Work will be commenced forthwith, but until the number of members is more considerable, no steps will be taken to obtain a charter. As we have already pointed out, the transactions of the Physical Society will have much to interest photographers, and we do not doubt but that we may obtain many valuable papers from that source, to place before our readers.

*The Electric Light in Photography.*—Artificial light has received but a very limited employment for photographic purposes, if we except its use for enlarging. Sunlight is so much more efficient, and so much cheaper, that circumstances need be very unusual indeed to call for the employment of the electric or oxyhydrogen or magnesium lights. The electric light was used many years ago by the Woodbury Photo-Relief Printing Company, to a limited degree, for printing the gelatine images, so that the operators might be independent of sunlight; and in Paris and elsewhere, magneto-electric machines, worked by means of small engines, have also been employed. In New York, however, for the printing of photo-engravings for *Leslie Journal*, there is a Wilde electric machine in constant use at the present day, and most satisfactory accounts are given of its efficiency. The electric light, as our readers know, is produced by a circuit of electricity being completed between two points close together (usually of carbon), and the cost of maintaining these, together with the expense of the steam or gas power employed for grinding the magneto-electric machine, constitutes the sum total of expenditure. The power of the electric light as compared to sunlight is very small. For instance, at eighteen inches from the carbon points the illumination is only one twenty-fourth as intense as sunlight on a bright summer's day; or, in other words, a photograph which would take ten minutes to print, or become blackened in sunlight, requires to be exposed to the action of electric light for a period of four hours to bring about the same result. Mr. Wilde estimates the cost of producing his electric light at the rate of fourpence an hour.

*Tinting Theatrical Portraits.*—There is one branch of photographic portraiture in which tinted albumenized paper may be employed with advantage. Where fancy costumes or theatrical characters are represented, such as are made to look best by gaslight, and which, as a rule, appear glaring and tawdry by the light of day, the employment of coloured albumenized papers does not come amiss. How very pale and chalky most of the robes and dresses that clothe actors and actresses look when rendered in a photograph! The searching daylight in the photographer's studio has, in truth, a tendency to deal rather harshly with drapery that appears so bright and charming at night; and thus it is that these pictures are never altogether successful. By judiciously choosing a tinted paper suitable to the subject, we think much might

be done to improve theatrical and fancy portraits, and give back to them some of their real character; or, better still, probably, would be the method of tinting the picture, after printing, by means of normal collodion to which a little (a few drops only) of aniline dye, thinned with alcohol, has been added. After the print has been mounted, touched, and rolled, it is held by finger and thumb, and a little methylated spirit poured over it; then the tinted collodion is applied, which runs uniformly over the whole surface, and dries rapidly upon the picture, covering the same with a pretty transparent film of colour. If desired, after the spirit has been poured on, pieces of thin paper roughly torn to shape may be placed over any portions of the portrait which are to be left white (face, arms, dress, &c.), the collodion being afterwards poured upon these shields, which adhere to the print when the latter is moistened with alcohol. Before the collodion has quite set, the bits of paper are removed, and the film dries up without any perceptible outlines.

*The Camera in Courts of Law.*—For multiplying legal documents, and letters upon which much value is placed in a court of law, photography comes in most aptly. In cases, when it is a question of peculiar formation in the words of a letter, of mis-spelling and other orthographical defects, the camera is the only trustworthy instrument that can be employed. In case the original is not forthcoming, photographic copies are proofs which cannot be gainsaid, but carry conviction with them against all the letter-press in the world. Why, therefore, should we not have a photographic department attached to our law courts, where documents in custody of the court could be copied as soon as they are deposited? The originals need then never be shown, while at the same time there would be no reason why properly authorised persons should not be supplied with these authentic publications, instead of merely a letter-press copy of them; for, as we have pointed out, it may not be the substance, but the words themselves, and how they are written, which is the most important. Of course a department of this kind would have to be properly organized, and conducted by responsible persons, as otherwise the benefits derived from it might not be altogether unalloyed. All documents and copies made would be in the custody of the court, so that no one could tamper with them. In the same way photographers attached to the department might be dispatched to various parts of the country, to obtain photographic evidence of places and things—services which, if undertaken by private individuals, might not be so fairly rendered, for, by being prejudiced one way or another, a photographer, as we all know, can influence a result, where it is not a merely mechanical rendering of a subject. There can scarcely be a doubt that before many years elapse photography will receive an appointment in our judicial departments, in the capacity of a recorder of evidence.

### FRENCH CORRESPONDENCE.

In presenting to the French Photographic Society some newer specimens of polychromic photography, which I spoke of in a recent letter as having attracted much attention, M. Leon Vidal mentioned certain modifications which he has made in the process. To-day I have received from the able inventor a communication concerning these recent improvements, and mentioning still another, touching the production of the various clichés required for the formation of the polychromic images.

In his first memoirs on the subject M. Vidal said, in a general manner, that it was necessary, in order to produce a polychromic impression, that there should be as many different clichés as there are different colours required for building up the image by superposition. This part of the process has been the subject of many objections; it was a complicated matter, and a costly one, and it was, moreover, next

to impossible to obtain clichés of precisely the same value as the original. Finding such objections really a hindrance to the process, M. Vidal has worked out a plan by means of which the clichés may be produced in a much more simple manner.

The problem to be resolved was, how to employ only the original negative to serve for all the impressions, and how, at the same time, this cliché mère, so to call it, might be employed without submitting it to any retouching, or tampering with its surface in any way. And these conditions M. Vidal thinks he has been able successfully to comply with in such a manner as to satisfy the most exacting. He produces all his reserves upon pellicles similar in composition to the material known as leather collodion (*collodion cuir*). These films are placed in close contact with the cliché mère, and the covering up or reserving of certain parts of the negative is carried out upon the pellicle, there being one for each colour, and the negative is printed successively with the different reserve pellicles against it, according to the colour to be produced. For small negatives, sheets of mica, very thin, may be used instead of sheets of leather collodion.

The preparation of the pellicle clichés in question is conducted as follows. M. Vidal commences by placing a pellicle of the requisite dimensions against the cliché mère, fixing it at three points, which correspond to three others on the negative. Two strips of paper, folded across the back and fixed with gum, keep the pellicle in its place against the negative, without any fear of its shifting. The pellicle is then worked upon, and covered with pigment to make it into a reserve, while the negative itself is untouched. In this way as many reserves are made as desired, a fresh pellicle being applied to the negative in every case, until at last as many pellicle clichés have been secured as there are tints required, each pellicle corresponding to a certain colour. By this plan of operating the original qualities of the negative or cliché mère remain unimpaired.

M. Vidal recommends the employment of clichés produced by the carbon process in preference to those obtained on dry collodion plates by contact with a positive on glass. The image obtained in the latter case is rarely of a clear nature. In fact, the film of collodion being more or less transparent, there is a diffusion of light, which cannot take place if the carbon process is employed, the bichromate mixture charged with black pigment being more uniform, and constituting a better screen. The black film prevents any diffusion of light through those portions of the film which have been acted upon.

Another important advantage of these carbon clichés on pellicle is, that they may be printed either from one side or the other, and a large number of them may be kept, stored up in a blotting pad.

A Marseilles photographer sends me a communication regarding sulphocyanide of potassium as a fixing agent. One of the defects of fixing by means of this compound was that the prints often assumed a dull red tint, and this fault M. Cayol removes by a very simple modification in his method of employing the material. He prepares two solutions of it of identical composition, each made up of:—

Water	...	...	...	100 parts
Sulpho-cyanide	...	...	15 to 20	..
Ammonia, sufficient to render the solution slightly alkaline.				

The prints are plunged into the slightly alkaline solution No. 1 for a period of four or five minutes. They are then taken out and submitted to a slight washing in water, and then plunged into solution No. 2, where they remain for another two or three minutes. After this, the prints are washed for an hour, and are then finished.

To be quite sure that the prints have been freed from every trace of sulphocyanide, a few cubic centimetres of a solution of sulphate of sesquioxide of iron is poured into a glass containing water which has been used in the last

washing operation. If no red tint is observable, it is proof that the washing has gone far enough, and the prints may then be deemed permanent. The solutions of sulphocyanide indicated above are available for a very long time if one only takes care to free them from any silver which they may contain, by placing in them, from time to time, sheets of zinc, and filtering the liquid before using it again.

Another correspondent tells me of a method he employs for producing bust pictures upon a black ground, by means of clichés of a perfectly graduated nature. The plan is simply to place in the camera, five or six centimetres in front of the sensitive plate, an oval two or three centimetres in measurement, cut out of cardboard or paper. In this way the negative produced will yield a black ground most perfectly graduated.

The same correspondent suggests an idea for correcting very hard negatives—a plan, by the way, which appears to me analogous to that employed by M. Denier, of St. Petersburg. A cliché which yields very hard prints, having been varnished, is covered with collodion on the reverse side, and it is afterwards placed in contact (without being immersed) with an ordinary negative bath by means of a suitable arrangement. The negative is then exposed again for a second time, diffused light passing through the image; or the plate is put into the camera and exposed at a white or grey background, put out of focus. A very short exposure is given, and the development follows with a weak iron solution. The second film of collodion is feebly acted upon through the clear parts of the negative, and proportionately in the other parts, the thickness of the glass itself softening down the result. In this way a hard portrait negative may be transformed into a soft cliché. ERNEST LACAN.

#### THE PRODUCTION OF ENLARGED LANDSCAPE NEGATIVES.

BY J. BRIER, JUN.\*

It is not necessary for me to say anything about the great advantage of being able to move about more easily, cheaply, and with less annoyance with a small photographic outfit than with a large one, as it is too well known. I do not wish to be understood to say that enlarging is easier than taking a moderate sized negative direct, as it is not so; for, at the least, three good plates have to be worked instead of one. The great advantage I consider to be that the tourist can bring the work home, where there is, or should be, greater conveniences, and so make himself less of a slave during what should be a pleasant out, if the weather be favourable.

In the first place, let us consider the small negative. The definition must be perfect, especially in the two corners of the foreground. It must be good in a pictorial sense, for though a large picture is superior to a small one, still, if it be not of a good subject, the smaller it is the better. The negative must have a full amount of detail in the shadows, and be vigorous without being too intense in the lights, only a small portion of which should be quite opaque, and this, if possible, should cut sharp against a deep shadow to give brilliancy to the picture. The negative must not have been printed from too often. If one which has been so used be examined with a magnifying glass it will be found to be full of minute black spots, caused by silver from the paper getting into the pores of the varnish.

Now a word about negatives to be taken for the purpose of enlargement. A good camera must be used, with the best plate glass, the full size of the dark slide. No carriers should be used, as, in my opinion, they warp, and have a great deal to do with imperfect definition. It is of the greatest importance that the lens be the very best that can be obtained, and "especially it must cover the plate well." I find, on looking over my old eight by five negatives with a magnifying glass, that though they are sharp enough

\* A communication to the Manchester Photographic Society.

for printing from, and as sharp as possible in the centre of the plates, still there is such a falling off in the definition towards the margins that they are unfit for enlargement. They have been done with opera-glass lenses and the front combination of a portrait lens. The process used should be one which gives a crisp image. Collodio-albumen comes first on the list; then the bromo-iodide dry plates, such as gun-gallic; next, wet plates, and those dry ones with a crystalline preservative, such as tannin. It is advisable that a magnifying glass be used in focussing. Plates should not be varnished until a good transparency be obtained. Collodio-albumen will do without, and the other dry plate and wet negatives should receive a coat of thin albumen while they are wet, which should be dried before the fire, as in varnishing.

I had almost forgotten to say anything about the size of negative suitable for enlargement. I think it best not to make them too small, as they not only have to stand more enlargement to attain a given size, but they are less fitted to do so; for, as the size of the plate decreases, it is more difficult to judge of the quality of the image. I should recommend not less than half-plate, nor larger than whole-plate size, the size of seven and a-half by five inches, commonly used by amateurs, being very suitable.

Now for the transparency. It should be made by contact printing on a plate larger than the negative, and of the same kind of glass, but thinner, for safety to the negative; for all but negatives on plate, thin, flat crown is best. The transparency must be full of detail in lights and shadows, and not too intense; it may be made by the Autotype or collodio-bromide process, but transparent albumen films seem to find most favour at present. I will describe the albumen process as I have last practised it, and I must not omit to say that I got a great deal of information from a paper, published about the middle of last year, in both the photographic journals, by Mr. Carbutt, an American gentleman. Take the whites of four fresh eggs, and add thereto ten minims of glacial acetic acid in half an ounce of water. Stir well together a minute or two, leave half an hour, then strain through a piece of coarse white calico, and next through a piece of the finest calico; then add fifteen minims of strong liquid ammonia. Dissolve twenty grains of iodide of ammonium, ten of bromide of ammonium, and ten of sugar-candy in two drachms of water; add to the albumen, and stir it well. Filter through a piece of moistened sponge cut to the shape of a cork, and fitted in the neck of a funnel. Polish the best side of a clean plate with a few drops of the albumen, using a piece of clean calico, warm the plate slightly, use the dusting brush, and coat with ripe, structureless, and thin bromo-iodized collodion. As soon as it is set, put it in a dish of water, rock it until the plate is no longer greasy, then wash well under a tap, for if the ether and alcohol be not entirely washed out the albumen is coagulated, which causes marks in the film. Now drain two or three minutes, with the bottom corner resting on blotting-paper; then coat with the iodized albumen; let the plate rest horizontal for three or four minutes, then flow the weak albumen into a bottle to be used for the first coat of future plates. Coat with the strong albumen four times, letting it flow from a different corner each time, and from the one where the collodion was poured from last rest this corner on a thick pad of clean blotting-paper, the top corner against a clean plate box, with the film inwards. Let it rest thus for an hour, then dry off before a clear fire, and, when nearly cool, immerse half a minute in a thirty or forty-grain aceto-nitrate bath, moving it about all the time. Then wash well, immerse in a weak solution of salt, wash, and flow with a three-grain solution of gallic acid, or, what is better, a strong infusion of black tea. Now leave the plate on blotting-paper as before, and if the room be tolerably warm it will soon dry. It is important that the plate be kept quite dry, or it will blister during development.

For exposing the plate under the negative I use one of the Autotype Company's printing frames, with a spring back in one piece only. I lay the negative in the centre of the plate glass (which, by the way, is nearly half an inch thick), then the albumen plate, taking care that the film side is next to the negative; next, two or three thicknesses of orange tissue paper; and, lastly, sufficient printing pads to give the required pressure. The pads must not overlap the negative, or the larger albumen plate will be broken; then the back is shut down until caught by the springs. Lay a focussing cloth over the front of the frame, go into the light, and make the exposure to the north sky, which varies from two to fifteen seconds for alkaline development, the average exposure to a blue sky being five seconds at present; but I think it useless to lay down any rule, as every one must find out his own exposures. I have no doubt that the magnesium lamp or the sciopicon would be the best thing to make the exposure with, as the light is always the same, and the exposure once found the density of the negative would alone have to be considered. The transparency would also be quite sharp, even if the contact of the glass were not perfect, so doing away with the necessity of using plate glass.

Now we come to the development. I prefer the alkaline method, for it gives an image of more even density over the plate, and freer from surface stains than when a hot solution of acid pyro and silver is used. Make a solution containing ten grains of bromide of potassium and one drachm of liquid ammonia to an ounce of water; take the plate out of the frame, flow it with warm water, and rest it horizontally while three grains of pyro are dissolved in an ounce of hot water, to which add five minims of the ammonia solution, and flow over the plate. If the image do not appear in about a minute, add more ammonia very gradually, and if the exposure be right the proper amount of detail and density will be obtained without intensification; but if the plate be over-exposed the development must be stopped before all the details in the lights are out, and intensified with two grains of pyro, one grain of citric, and ten minims of acetic acid to the ounce of water. Flow over the plate, and then add three or four drops of a ten-grain solution of nitrate of silver. If the image is very fully exposed use more silver, but if it have not sufficient detail in the lights warm the solution, and keep the quantity of silver as low as possible. If a slight fogging occur at any stage of the development, flow the plate with water, and rub lightly with a tuft of carded cotton. The fixing must be done in a half saturated solution of hyposulphite of soda, made milky with acetic acid. When developed by the alkaline method these plates require no toning.

And now we come to making the enlarged negative. I shall not say anything about the camera or enlarging room, but confine my remarks to the lens and process. First, what is the right sort of lens to use? I think that for anything containing no straight lines a single lens of not less focus than the length of plate to be enlarged will give the "sharpest" image. The lens must be reversed, or the marginal definition is very poor. A doublet lens, having both the combinations symmetrical, is a very excellent lens for enlarging, as it works quickly. In my opinion, there is none worse than a portrait lens, which, however, will do pretty well if it be a good one of moderately long focus, with a small stop, and reversed, which I must explain, for the benefit of beginners, does not mean turning the lenses round and in their cells as I once did, but turning the tube end for end, so that the cap of the lens is next to the larger plate.

And, lastly, the process (of course there is nothing so convenient as the wet process) is developed with a fully acid, weak iron solution, to which you can add some strong solution if the plate be under-exposed; but if the lens be quick, the light good, and the transparency thin, I think the best results can be got on the ordinary collodio-albumen plates with alkaline development.

## MY TROUBLES IN TAKING LARGE DIRECT HEADS.

BY R. W. ALDRIDGE.\*

ALL being now ready for the venture, we determined to try one of the 15 by 12 plates. Having fitted a rounded wooden top to the neck of an earthen jar, and stretched a piece of flannel over it, we were enabled to coat the plate balanced on the top, or to develop without any difficulty. Our first plate, however, was one mass of fog, with a most ghostly image dimly discernible in the centre—the mere shadow of a shade! There was evidently something amiss with the bath, but it was difficult to say what, as it seemed all right by the usual tests. I consulted my friends: one advised boiling, another the precipitating of the newly made bath, and a third that it should be let alone till it came right of itself. With two or three days' sunning, however, and the addition of a little nitric acid, I got rid of this trouble. It was nevertheless evident, from the brown colour of the bath, that the silver was gradually dissolving the mixture of tar and pitch with which the interior was coated. I was obliged to filter nearly every day, and was much troubled with pinholes. Eventually I found it expedient to give up both bath and dipper. I procured a large gutta-percha cradle bath, capable of taking a plate 17 by 23, and have found it answer very well. For my next dipper I procured a strip of ground glass  $\frac{1}{2}$  inch thick, 3 inches broad, and 29 inches long. I got the glazier to cut off two pieces about  $\frac{1}{2}$  inch broad from the end. These two pieces, after being ground so as to retain the plate, were fastened one at each end with marine glue. This dipper has done me good service. I submit it for your inspection. As you will see, it is a substantial article, and not to be broken by a trifle. I confidently recommend the plan to any one who requires a dipper of extra size. The cost was sixpence.

Having thus got over the mechanical difficulties, I resolved no longer to do the thing by halves, but to try the large size. Here I met with the last and greatest trouble of all: none of my models came up to the required size. I contend that a majority of the large direct heads exhibited were really, however unconsciously on the part of their authors, enlargements upon the natural size of the models, more especially the female faces. In order to show that I am not alone in this opinion, and that they produced upon others this disagreeable feeling of exaggeration, I will give you a few extracts from the critiques upon these heads that appeared in the daily press. I have avoided, as far as possible, all personal allusions.

*Globe*, October 24th.—“Owing to the fact that prizes have been offered for large-sized heads from nature, the exhibition is full of ambitious effort; it is also full of failure.”

*Daily News*, October 25th.—“The efforts of the artists who apply themselves to taking large pictures direct deserve praise; but in the meantime these portraits, when they get to life-size or beyond that, are far from satisfactory.” Another extract from the same says:—“The heavy masses of black shadow, the ghastliness of the white surfaces (in some cases the complexion that of a corpse), and the general look of hardness and exaggerated prominence of feature, show that the indefatigable efforts of artists and amateurs have not yet been followed by success.” Further on the critic mildly alludes to the pictures as “these gigantic nightmares.”

*The Daily Telegraph*, October 25th, says, speaking of Colonel Wortley's heads:—“These and one or two others from the hand of the same distinguished amateur are of heroic rather than life-size.”

But I will not cull any more of these flowers of rhetoric that so plentifully bestrew the critical garden. I have, I think, quoted enough to show that these large heads con-

veyed to what I may call the outside world an effect of exaggeration, not merely in the features, but in the sizes of the heads themselves. Do not think because the difference in size is small—merely an inch or so—that therefore it must be of trifling import; the difference between success and the want of it is often owing to the presence or absence of what appears of small importance. It is the *little more* or the *little less* (as the Italians say, “Il poco pin o il poco meno”) that makes all the difference. One thing was unanimously allowed: that the smaller series of 5 $\frac{1}{2}$ -inch heads was decidedly superior to those competing for the first prize. I think this may be easily accounted for. In the first place, there is no lens that is really equal to the work of taking, without exaggeration, and in such a time as to render the work really practicable, a life-sized head. It is pretty generally acknowledged (if anything in connection with photography can be said to be settled) that the D lenses of Dallmeyer are those best suited to large heads or figures. They have the disadvantage of being exceedingly slow, but have considerable flatness of field, while an attempt, at least, has been made, by diffusion of focus, to overcome that greatest of all objections to the use of large lenses—the want of depth. The disadvantage attending the use of single or landscape lenses being the coarseness of the rendering and loss of half-tint, I used a 7D (that is, a 5-inch) lens, with a back focus of 24 inches. This is the largest size generally made; in fact, I never heard of any one who has a larger, except Mr. Crawshaw, who uses an 8D. To obtain a head of the size of life, I had to bring the front of the lens within 5 feet of the sitter. This was bad enough, for exaggeration of the more prominent parts follows as a matter of course. The principles of perspective are violated. The human eye can only take in at one time what is contained in an angle of sixty degrees. If I approach so near to an object as to command a greater angle of view, distortion follows exactly in proportion as that law is violated. Dallmeyer, in his pamphlet on lenses, observes:—“What is the proper distance at which to place the subject from the lens?” In answer, it may be safely asserted that it should, as a rule, be not less than 12 feet, nor perhaps more than 24 feet; for if less than this the resulting picture will probably be defective, both in definition and perspective, because the lens producing it will be of too short a focus. Thus you perceive that while the maker of the lens cautions me not to go within 12 feet, I am obliged, in order to get a life-sized head, to bring the lens within 5 feet.

Then came the other trouble I have spoken of. I placed the model (a lady), and went with my strip of cardboard to measure her face, as I have explained in a letter in the *News*: exactly 6 $\frac{1}{4}$  inches. This, of course would not do, but by moving the lens about a foot nearer to the figure I got the right size, but everything else was wrong. Fancy, too, the huge Cyclopean eye of the lens staring into a lady's face at less than 4 feet distance, and you may imagine the elongation of the facial muscles that followed. I next tried my assistant, who is about 5 feet 10 inches in height: a face of 7 inches. I tried several others, but they were below the standard. At last I found exactly what I wanted, so far as size was concerned—a face of 7 $\frac{3}{4}$  inches. As my friend was wounded at Waterloo, where he was a captain of cavalry some fifty-nine years since, he can scarcely be called a young man, but having sat without flinching for smaller portraits we determined to try the life-size.

You will scarcely be surprised to hear that, after three sittings, varying from three to five minutes (for I had taken out the stops, so as to approach as nearly as possible to the instantaneous), although my sitter had borne the infliction with the patience of a martyr, there were signs of movement in every one. My friend would not acknowledge that he could have moved, and attributed the apparition of a spare nose and sundry additional eyes, to the head-rest or the shaking of the floor. I have a skeleton studio in the garden, so our next attempt was made there.

\* Continued from page 87.

The light, however, was not first-class, and I hit the time exactly with a two minutes' exposure, using a number two stop, and removing it during the sitting. But again the double nose appeared. My friend the colonel attributed this untoward event, as the Duke of Wellington styled our victory at Navarino, to the shaking of the table or the rotation of the earth, I forget exactly which; one thing, however, I remember perfectly: it was *not* to his having moved. No doubt the length of the exposure was partly due to the advanced season of the year, for by the time that all things were in order, and I had got through the preliminary stages of my troubles we had come to the commencement of October. Following the directions of Dallmeyer, when I brought the lens so near to the figure, I diffused the focus of the lens by giving nearly four revolutions of the screw. This, of course, takes off considerably from the sharpness of the head, but is necessary, in order to get something like evenness in the definition. I think the best effect is obtained by a combination of this diffused focus with the use of a small stop. Of course, this must add very materially to the already very long exposure.

At the risk of being tedious, I have entered into these details respecting the large D lenses, as I do not find their management is generally understood. Mr. Blanchard, who uses a lens of this construction, once observed to me that they require an apprenticeship to use them properly. A letter from Mr. Samuel Fry has lately appeared in one of the journals, stating that by the improved construction of his studio he had been enabled to reduce the time of exposure required by a 7 D most materially. As his experience differs very much from mine, I shall, if possible, avail myself of his kind invitation to witness these results. Mr. Fry makes one very valuable suggestion: he proposes that the side light of the studio should be made to slide along, so that the light may be admitted without any obstacle. For some time I have been contemplating such an alteration with regard to the top light. Why should we not apply the principle to both? In the summer season it would not only shorten the sitting, but add materially to the comfort of the sitter.

And now, gentlemen, I approach the end of these troubles. The obstacle with regard to the more than life-size heads prevented me from competing in that class, and I contented myself by sending three of the smaller size on 15 by 12 plates. As I never expected that one who has had so little practical experience of this kind could successfully contend against the giants of our art, I experienced no disappointment at my want of success. I rather console myself with the reflection of the old Greek poet. "In great attempts 'tis glorious e'en to fail," and rejoice that the art I love has better followers than myself.

If I may be allowed to sum up the results of these random observations, I must admit that for extreme sizes the enlarging processes are easier, cheaper, and may be used in many cases where the large lens cannot. As far as they will properly go, however, I believe in the direct pictures. They have more force, depth, and brilliancy; more detail, and, I believe, more refinement. If we refer to the acknowledged leaders of our art science, we shall find their success is owing to their larger and bolder work; none of them owe their reputation to any enlarging process. The aspiring photographer will not be contented with a dull mediocrity. He will strive not merely to equal the works of his competitors, but will endeavour by all possible means to extend the bounds of the art he follows. Can such a man be content to stop at carte negatives? I boldly answer, No.

#### PHOTOGRAPHING THE TRANSIT OF VENUS.

Mr. J. AITKEN gives in *Nature* the following hints on what is known as "blurring," but which he styles "irradiation."

"The following is the result of some experiments recently made on photographic irradiation:—

"If, as is generally supposed, photographic irradiation is caused by the reflection of light from the back surface of the plate, then photographs taken on non-actinic coloured glass ought to be free from irradiation, because the light would be quenched in the glass, and therefore no reflection could take place. Photographs of a model transit were taken on yellow, orange, and red glasses; but in all cases the irradiation was nearly as bad on the coloured glasses as on the clear glass.

"Photographic irradiation may possibly be caused, either by the bright light producing an intense state of chemical activity, which has the power of spreading itself, or, what seems more probable, the parts of the collodion on which the bright light is falling become luminous, and reflect light to the surrounding parts of the sensitive film, and thus extend the chemical change in each side of the true optical boundary line. If this is the explanation, then we can correct photographic irradiation by allowing only sufficient light to fall on the plate to produce the necessary chemical change, so that there shall be no surplus to be reflected: or we may make the sensitive film of such a nature that it cannot reflect the actinic ray. There are two ways of carrying out the first of these plans. We may either 'stop' down the lens by means of a diaphragm, or we may pass the light through a non-actinic coloured screen. The first should be the best plan, but was not found practicable with the Dallmeyer 'triplet' lens used in the experiments. Screens of glass and coloured solutions were then tried, and photographs of the model transit taken perfectly free from irradiation, and not to be distinguished from photographs of the model taken against a dull sky, which required fifteen seconds' exposure. Experiments were then made to make the sensitive film incapable of reflecting actinic rays. This was done by adding red aniline to the collodion, till the colour was found by experiment to be deep enough. Photographs taken in this way were also quite free from irradiation. After the photographs were developed and fixed in the usual way, they were treated with chlorine gas, which destroyed the red colour, and left the photographs on a clear film.

"Ocular irradiation is also, in all probability, in part caused by the reflection of light in the eye. But in addition to this cause there is another of considerable importance—namely, the 'persistence' of the image combined with the unconscious motion of the eye, as the impression received by the brain is not only that of the light on the part of the retina where the image at the time is, but also that of where it was a short time before; the mental impression must, therefore, be larger than the image on the retina. Ocular irradiation can also, in all probability, be corrected by reducing the amount of light falling on the eye to the minimum necessary to give a distinct impression. The reflection in the eye will then be less, the image not being so bright will not 'persist' so long, and the light not being so brilliant the stimulus to the unconscious motion of the eye will not be so great. Diaphragms will, of course, be preferred for this purpose. When screens are used it is probable that neutral-tinted ones will be found to suit best."

CHLORIDE OF SILVER AND CONCENTRATED SULPHURIC ACID.—The *Chemical News*, quoting from the *Zeitschrift für Chemie* speaking of some experiments by A. Sauer, says:—"It is commonly stated that chlorido of silver is not attacked at all, or but very slightly, by concentrated sulphuric acid. This is incorrect. If chlorido of silver, either recently precipitated and washed, or crystallized, or fused, is heated for some time with concentrated sulphuric acid in a covered porcelain capsule, the chloride of silver is decomposed and dissolved, with escape of hydrochloric acid. Chloride of silver is also soluble in solutions of perchloride of iron, a circumstance which should not be lost sight of in determinations of silver."

## RESTORING THE SENSITIVENESS OF BROMIDE OF SILVER.

ONE of the special advantages which in the old times the Daguerreotypist possessed over the modern photographic portraitist consisted in the fact that a Daguerreotype plate which had been exposed to the action of light could be re-sensitized. A few moments' exposure to the fumes of iodine removes any image impressed by the action of light, and restores the normal sensitiveness of the plate. In any case where a sitter has moved, and so spoiled the portrait beyond redemption, or in a case where the plate has been accidentally exposed to light, the remedy was simple and the plate was not wasted. The collodion worker possesses no such remedy in case of a plate spoiled in exposure.

The action of light, if it fail to produce a satisfactory negative, spoils the plate beyond remedy. Hence the anxiety of the portraitist when called upon to take trouble some babies, and the waste of time and plates produced by restless sitters. Cleaning the plate, coating the plate, and exciting the plate, involving waste of time; the expenditure of collodion and nitrate of silver involving waste of material, all become useless if a finger be moved by the sitter. No treatment with iodine will effect a remedy. Immersion in a solution of an iodide will remove the image; but it will also destroy the sensitiveness of the plate.

There is reason to believe that the characteristic possessed by the Daguerreotype plate also distinguishes at least some bromide emulsion plates. After exposure to light they may be re-sensitized. Mr. Kennett, to whose gelatino-bromide emulsion we recently referred, describes a very interesting experiment in connection with this subject. One of the bromide plates which had been exposed freely to diffused light was immersed to the extent of one-half in a solution of bromide of potassium, and then the whole exposed under a negative and developed. The half which had not been immersed was, of course, one mass of fog, and no trace of an image. The half which had been subjected to the solution of bromide gave a perfect, vigorous image. This fact, if verified in further experiments, points to some interesting and important possibilities. Not only may a plate spoiled in exposure in the camera be re-sensitized and again used, and plates which have received accidental exposure to light in travelling be also restored in a similar manner, but the sensitive dry gelatine sold for preparing emulsions acquires an immunity from risk of a most valuable character. One of the difficulties attending the vending and use of such dry sensitive gelatine would be the constant danger

of an occasional accidental exposure to light. But with this facility of re-sensitizing, no trouble need arise from such exposure, as a few moments' treatment with a bromide solution would destroy the effect of light, and restore the normal sensitiveness. How far the same fact may be found true of all bromide emulsion plates it is impossible at present to say. In those in which free nitrate forms an essential element it is manifest that a difficulty would arise. At any rate, the question is an interesting one, and the possibility involved may give a new element of value to all bromide emulsion processes.

## THE RIGHT TO ONE'S FACE.

It is a common complaint amongst professional photographers in this country, that the social status of the photographer, as a photographer, is of a less assured character than it ought to be; and there is, unquestionably, some ground for the complaint. Amongst the many causes which have some influence in affecting this social status, the ready tendency of some writers in the public press to assume the worst, and then proceed to argue upon such assumption as fact, is one of the most important factors. In the correspondence which we printed last week on the subject of copyright in portraiture, this tendency was shown, and it is fully maintained in an article on the same subject which appeared in the *Standard* a few days ago. It is assumed that a practice commonly exists amongst photographers of exhibiting or publishing the portraits of their sitters without their leave and against their protest. "People complain," it is said, "that they find themselves staring at unauthorized portraits of themselves in shop-windows, and often not in the best company." As a general statement, nothing could be more untrue. No respectable photographer publishes unauthorized portraits. Indeed, if any man were foolish enough to do so, he would find that it did not pay, as he would ruin his reputation and connection at once. Such a thing may occasionally have been done by some thoughtless or unscrupulous photographer, but the rule amongst portraitists is not to part with a single copy of a private portrait without the authority of the sitter. The supposition, indeed, that private portraits would be of any value for publication, and that they are likely to be paraded in "the sight of all Cheapside, the Strand, and Fleet Street," as the writer in question suggests, is absurd enough. But as for portraits of public characters, which may be seen in these and other thoroughfares, this writer should know that they are taken expressly for publication, with a perfect understanding as to the purpose; and that "Lottie Peachblossom," or "The Great Bounee," agree to such publication, because it helps to popularise them, and the time may come when that popularity may enable them to exact a royalty from the photographer on the sale of the portraits which at one time they would willingly have given a premium to promote. Here is the article from the *Standard*:—

It is asserted as a grievance that a man has no right to keep his own face to himself and his friends—in other words, that he has not a copyright in his countenance. People complain that they find themselves staring at unauthorised portraits of themselves in shop-windows, and often not in the best of company. Nor is the complaint altogether unjustified. The facilities of photography are certainly abused by many of its inferior professors, although the art itself is growing into greater value daily. There are some who affirm that it has exercised an injurious influence, by superseding in a large degree original drawing, steel engraving, lithography, and sketching from nature; but there appears no serious evidence of this, while, on the other hand, we have had almost the whole architecture of the world which was worth copying brought home to us by the process, as well as the pictures, the statues, and the antiques in every gallery. At the same time, a race exists of photographers only half-trained to their work, who misuse the light of heaven by the multiplication of blots on card-paper supposed to be portraits; and hence a general nuisance in the shape of albums, presenting every possible variety and distortion of feature, the pages of which politeness compels the weak-minded to turn

over, and ugliness, which the same weakmindedness is compelled to praise. But the mischief does not stop at this point. It is bad enough that in nearly every drawing-room a batch of commonplace visages is paraded for inspection, from that of some old butler to that of the newest and most beautiful baby in the land; there is the chance of being seized upon, unconsciously, by the photographer, and turned into material for his tout, or for an illustrated newspaper, whether such publicity be agreeable or not, and whether or not the delineation be faithful or a mere slander in light and shade. There are persons not a little sensitive in the matter who object to seeing their lineaments exposed to the common gaze all the season through merely because they happen to take well, and the artist thinks he has not reaped his legitimate profit when he has pocketed the amount of his charge. Naturally, too, there are others who, disgusted with the photographer's failure, throw it aside, and are annoyed to see it disgracing them in the sight of all Cheapside, the Strand, and Fleet Street. The evil is a petty one, no doubt; but as a matter of right, when the photographer has fulfilled his commission, and has been paid for it, is it legitimate for him to make a market of his sitter? Without an express stipulation to the contrary, Mr. Leighton informs us he can legally do so; but, when Parliament has time for these minutiae an Act might remedy the wrong; though, for our own part, we should prefer trusting to the repudiation of the practice by the more respectable masters in this most popular department of art. It might be impossible to restrain the multiplication of faces belonging to public men—statesmen, members of Parliament, distinguished writers, great travellers, philanthropists, and so forth—because they live in the full glow of the sun, and must expect to figure in the galleries of even cheap and bad photography prior to being immortalized by cheap and bad wood-engraving. Nor, in the main, are they averse from this sort of celebrity; and so with actors, actresses, singers, who, however, are careful as a rule to permit no portraits of themselves to be taken unless with a flattering effect; and then the more their identity is blazoned the better are they pleased. But there are thousands imbued with a strong repugnance to a shop-window notoriety, and especially so when they may hit upon their portraits displayed side by side with others of a not too unequivocal character. It is a fact that the photographer, when he happens to have as a sitter any one possessing beauty, and whose portrait makes also a picture, continually converts the negative to his own use, frames a graceful face for his doorway, and thus tempts the vanity of the passers-by. The trick is one thoroughly well-known, and it ought to be scouted by the more reputable class of the profession itself. Not that any actual harm is done, although painful errors might, no doubt, arise; but to have the face of a wife, a sister, or a daughter, hawked about as a specimen of the work turned forth in a particular studio, is, to say the least, far from pleasant, though, as a matter of fact, the photographer has a perfect right to crowd his entire window, if he chooses, with representations of a single countenance, and thus make it the talk of London. It is not so with art-galleries. In most cities of Europe a regular code of restrictions is enforced upon copyists and photographers; while at Dresden and Munich the only complete sets ever taken were for the Kings of Saxony and Bavaria. Socially, however, the custom is becoming intolerable. Any one who has ever been photographed may, for example, should he happen to be a conspicuous witness at a trial, behold a blurred and abominable thing purporting to be a semblance of himself, as an illustration in the pages of an amateur police gazette. Mr. Leighton's story of Madame Rachel, into whose room when she lay dead a photographer obtained admission, producing a ghastly caricature, which he sold as "from the life," is only an exaggeration of the pestilent habit prevalent among ourselves.

The unauthorized exhibition of portraits in a photographer's specimen-case might, it is true, become an occasional annoyance, but few photographers would persist in such exhibition against the expressed wish of a sitter. In any case, the possible grievance is of too insignificant proportions for lengthened discussion in the public press. It is unauthorized publication, if such were common, which could alone justify such public protest. If such a practice existed, the plan recently suggested by Mr. Beau, of giving the sitter the assurance of safety involved in registering the copyright in his name, might be worth adoption. As the matter stands, we can scarcely see that any evil exists in the matter calling for remedy, unless it were possible to check the publication of the mistaken notions of alarmists who remain pertinaciously ignorant of facts.

Mr. Whitfield, of the well-known firm of Lock and Whitfield, writing to the *Standard*, confirms our statement of the practice of respectable portraitists. He says:—

SIR.—In an article on copyright in photography, in your edition of Friday last, you ask, "Is it legitimate for the photographer to make a market of his sitter?" I say certainly not, if his sitter has commissioned him to take a portrait, and pays him for so doing. At least this is the way, I believe, the law, whether rightly or wrongly, has always been viewed by the profession, and I never heard of any photographer having the audacity to publish copies of portraits that have been executed on commission without obtaining the express sanction of the sitter, or, in case of his death, of his family. If this is not really the law, the sooner it is made so the better. Photographers, I consider, not only have no right to publish without permission, but they ought to be very careful how they part with portraits to any one, even to members of the sitter's family, without his written authority. But if the law is uncertain, the best way to prevent an improper use being made of the negative would be for the sitter to purchase it, and keep it in his own possession, employing whom he chooses to print from it.—Your obedient servant. G. C. WHITFIELD.

#### DISRUPTION IN THE PHOTOGRAPHIC SOCIETY.

AMONGST the various comments and suggestions on the present crisis in the society which reach us from various quarters, one or two ideas seem to have acquired general prevalence. A wide spread feeling exists to the effect that there is something supremely absurd, if not absolutely illegal, in the notion that the government and probable future of a society, numbering three or four hundred persons residing in all parts of the United Kingdom, should be destroyed by the combination of a couple of dozen persons. And the outcome of this idea is a prevalent feeling that some early steps should be taken to elicit the views of all the members on the proceedings at the late special meeting and annual meeting. The question is asked, whether, in an emergency like this, a *plebiscitum* should not be taken. The answer is very simple. A general decree of all the members should, undoubtedly, be the final appeal in such case, but how is it to be secured? Those now in power, legally or illegally, are not likely, as a correspondent suggests, to take a course which would probably put a summary end to that power; and there is neither stand-point nor fulcrum for outside action.

We do not at present see light. There are some signs of disorganisation in the new camp. On another page we print a letter from Mr. Thomas, who accepted a position on the committee appointed by the requisitionists, solely with the hope that he might be able, in the emergency, to do some service to the society. With the natural instincts of a high-minded and honourable gentleman, his first aim was to make an appeal to the general mass of the members, which such a crisis demands. Such a course did not accord with the views and purposes of those who have recently attained the reins, and finding his aims for the society hopeless, Mr. Thomas has found it necessary to resign. We have heard of another gentleman, one of the most energetic and capable of the requisitionists, who contemplates the necessity of leaving his party, and placing himself in antagonism to them. What may be the outcome of all this we cannot tell.

In a letter from Mr. Sawyer, another gentleman associated with the party in office, it will be seen that a most important admission is made—an admission which may be satisfactory to those of the council who have advocated the rights of the country members, as it shows that the arguments have not been quite thrown away. The "time has come," it is admitted, for "considering" the "important step of admitting every member of the society to the right of voting and nominating, quite irrespective of their presence or absence at any particular meeting." This is a most important concession. Only a fortnight ago the rule which made personal nomination imperative was insisted upon as the very basis of any modification of the laws. Any committee formed was to be trammelled with this as

an instruction. Personal nomination in open meeting was then a corner-stone of the new structure. Now, thanks to the cogent logic of the speakers and writers on the side of the council, some of the requisitionists are willing to get rid of this corner-stone as soon as they can decently drop it. The subject will be "considered," and if the process of consideration be not too long, there is hope for the society in this.

The notion of a national society seems also to be gaining ground, but the general attitude of all concerned remains one of waiting expectancy.

### THE ACCELERATING EFFECT OF COLOURED LIGHT ON SENSITIVE FILMS.

BY W. T. BOVEY.

THE accelerating effect of diffused light when applied to a sensitive film prior to its being exposed, under ordinary conditions, in the camera, has of late excited considerable attention, and much ingenuity and fertility of resource have been developed by experimentalists, who have investigated this important matter with a view of advancing another step in the direction of instantaneous photography. These—unanimous in their recognition of the principle—differ only in the obstructive medium they select for reducing the intensity of solar light to a requisite degree of dilution. Now, in reference to this interesting question, placed—not for the first time—before the photographic world, it has occurred to me that in this, as in all other branches of scientific research, success in a great measure depends on an acquaintanceship with ruling principles, as, without such knowledge, experimentalists must needs go groping in the dark, trusting to lucky accident or blind chance for a successful issue to their labours. Prompted, therefore, by the consideration indicated, I am tempted to trespass on grounds of theory, that I might extract from speculation some lesson which might prove capable of a practical—perhaps a useful—application; and to realize this object in view, it is necessary, in the first place, that we enter briefly on an enquiry having reference to actinic influence, as evidenced by its effects on a chemically prepared and sensitive medium.

Concerning this matter we already possess certainty, from the teachings of experience, that with the camera pointed skywards, an almost instantaneous exposure suffices to reproduce beautiful cloud forms, perfect in softness and absolutely correct in detail. We also know that if the exposure is prolonged but a few seconds, that the sensitive salts spread evenly over the plate become uniformly excited, and, under such conditions, all trace of form is lost, and an opaque ground springs up under the action of the developer. If the time of exposure is further increased, the magnetic and latent force diminishes conversely with the added length of exposure. Pushed to extremes, the developer ceases to act in the usual way; bare glass is shown as the result of the experiment.

And thus does it arise, as I have some time since pointed out, that lights and shadows of a given object might easily be reversed by prolonged light action on the plate placed in the camera; and from this ascertained fact we learn that the immediate operation of actinism when brought into contact with the sensitive haloid salts of silver, *plus free silver*, is to induce the several stages of decomposition, or, rendered in other words, a partition of the combined elements. As, for example, light, in its first contact with a sensitive film, produces a molecular disturbance which might, perhaps, be likened to the effect noticed when a piece of steel is held near a balanced magnet. There is nothing definite beyond a tremulous motion and a divergence of the needle from its normal position, which returns to its natural position when the cause of disturbance is withdrawn. But, unlike the magnet, the molecular disturbance wrought on a sensitive surface by light produces a permanent change of structure which possesses the peculiar property of attracting to itself the

silver set down by the reducing agency of the developer. But in the event of the light being filtered through coloured glass—which, by the way, is only a convenient method of producing semi-darkness—the disturbing force, whilst sufficient with brief exposure to overcome the vis inertia of the chemical combination connected with the sensitive medium, is not sufficiently strong to carry the decomposing influence to that stage which sets up magnetic attraction, which is capable of acting in concert with the developer. Subsequently, on receiving exposure in the usual way, the requisite conditions are produced with a saving of time that must, under other conditions, have been consumed in overcoming the inertia before referred to.

Hence, then, we learn that any advantage derived from what I might term initiatory exposure must entirely depend on that exposure being so nicely adjusted as to be stopped immediately within the threshold of that stage when magnetic action is set up, otherwise fog is inevitable, and ruin to the negative must be anything but doubtful.

I am strongly inclined to believe that, in order to make this new aid to sensitizing a practicable help, a steady, uniform, and at all times reliable description of light is necessary. Such, I scarce need observe, is not to be procured, in our changeable atmosphere, from the solar luminary. It would therefore be advisable to have recourse to some kind of artificial lighting, such as gas, paraffin, &c.; these, varying but slightly in actinic intensity, would enable the operator—having first proved by experiment the limit of exposure that is free of danger in the direction of fog—to time his primary exposure within such limits; and thus may he secure all the available advantages possessed by the new power placed in his hands.

The principle embodied in this novel method of accelerating exposures is one that I have often found useful to me in my printing operations, more particularly in the work of printing in natural colours. As, for example, I desire for a landscape a horizon bright and sunlit, with fleecy clouds traced in distance. Well, I have only to arrange the mask in such a way that feeble light is diffused, and gets admittance beneath the arched covering. Too weak to include visible printing, yet sufficiently strong to create latent forms, the effect is not seen until the print is removed from the frame, when a few seconds' exposure to diffused light brings out the before unseen clouds, and the result sought for is thus easily procured.

Whilst these last remarks impart a lesson worth learning, they also point out the necessity of avoiding semi-transparent spots, that are sometimes the result of imperfect painting out of skies. On removal from the frames the sky parts appear white and faultless; but on tinting down those whites, out jump dark spots. "Oh, that abominable paper!" (the ordinary seapegoat for all photographic disasters). Forgive the paper for this once, dear reader, as a little agitation over the irregularly produced spots I have alluded to will impart a deal of information to your understanding respecting the principles embodied in the mode of accelerating exposures, to which, in this chapter, I have endeavoured to enlist your careful and heartiest attention.

### Correspondence.

#### DISRUPTION IN THE PHOTOGRAPHIC SOCIETY.

SIR,—It is with some regret that I find myself, in starting, at issue with the members of the committee who have been elected by the Photographic Society with the new council to revise the rules for its conduct. I feel strongly that, under the circumstances which have brought about an event without precedent—viz., the resignation of all the officers of the society—it would be most desirable and politic, before presenting new rules at the next meeting, to test the feelings of both the metropolitan and country members, by circular, as to their views regarding the one point about which the retired officers and the requisitionists are at variance, and then to act on the result so obtained.

As this suggestion has not at present met with a favourable response, I am obliged, as one of those who voted with the council, to withdraw from the committee at this stage of its proceedings.—I am, sir, yours very obediently, RICHD. W. THOMAS.

#### DISRUPTION IN THE PHOTOGRAPHIC SOCIETY.

SIR,—As one of the numerous country members of the London Photographic Society, who are totally ignored by the party who have deposed the president and council, I should like to say a few words.

First, I wish to know why I received no ballot paper, as post-cards were sent stating that ballot papers would be sent to all *bona fide* members who had paid their subscriptions? I am a member of the Junior United Service Club, London, containing two thousand members; and on important occasions like those affecting all the members, ballot papers are sent to all the country members. If the country members are to be ignored, as they have been, in the London Photographic Society, I, for one, shall not long remain a member, and many others will, no doubt, agree with me.

As regards the action of the requisitionists, who have turned out the president and council, I consider (as a member) their conduct factious and discreditable, after having carefully perused all the correspondence in your columns, including the letters of Mr. Hughes and Mr. Stillman.

As a member who has been ignored, I, for one, shall ignore the acts of the so-called new vice-president and council, and I consider that they should be got rid of by a vote of *all* the members, in order to clear the ground for reasonable amendment in the laws of the society. If this is not done, the society will become a mere local clique. The requisitionists may be likened to Korah, Dathan, and Abiram, who "took too much upon them." Our rebellious spirits have taken far too much upon them to presume to act for the whole society.

I think it would be well if some course were indicated, Mr. Editor, through your valuable columns, to all country members of the London Society, how to act in concert in order to depose this self-elected council.

Colonel Wortley's suggestion for a national society deserves the consideration of all amateur and professional photographers really interested in the advancement of the photographic art.—I remain, your obedient servant, FRANCIS W. TURTON,  
Bedford, February 23rd. Commander, R.N.

SIR,—I presume that all well-wishers to photography, whether they reside in London or the country; whether they are engaged in any form of photographic business enterprise, or are simply interested in the beautiful art as amateurs, must cordially agree with a correspondent in your last, in hoping that some method may be found of inducing the council to resume their duties for the present year, and, when a perfectly revised code of rules is provided, gracefully place their offices at the disposal of the members. The result of a universal vote of the society would beyond a doubt place the majority of the council again in the position which they have, for photography, so beneficially filled. But I fear that this very fact is the greatest obstacle. The retrogressionists—I use the word advisedly—now in power probably know as well as any one that their power would be destroyed by any universal vote, and are not likely to seek such a general expression of opinion and direction. The society has nothing, I fear, to hope from any graceful steps on their part towards the late council; and, I fear, equally little to hope from any energetic independent members, most of whom seem too much disgusted with the success of a petty conspiracy to take steps of any kind.

The one thing which now seems to be desirable is to obtain a *plebisitum*. But how? The new rules of the requisitionists not only make no provision for the vote of country members in electing officers, but they expressly stipulate, on the contrary, that no one shall ever propose or nominate an officer unless he attend the January meeting for that purpose; and he must again attend the February meeting to vote. Until, like the fabled monster which swallowed its own offspring, the requisitionists destroy their new made rules, the society can have no hope from the aid of country members. Can you suggest any way out of the difficulty?

There are one or two more questions I wish to ask. The new officers being said to be illegally elected, can they spend the funds of the society? Is the balance of £300, referred to, safe? If a national society be formed, can the general voice of the present society hand over the funds to the new society?

SUUM CUIQUE.

SIR,—It is a misfortune that the crisis through which the Photographic Society of London is passing should have been productive of so much embittered feeling, and given occasion for such a leading article as appears in your journal of the 13th. You have an undoubted right to your opinions, and also to the advantage in their expression which your position as a journalist affords. I therefore ask to be heard in defence of what I believe the only course by which energy and vitality can be infused into a society which, from its position, should have been the head and leader in matters photographic, not only in London, but in all places where photography is cultivated by Englishmen.

(1) In my estimation, the principal causes that have led to this disruption may be summarized as follows: the government of the society has become practically an oligarchy; the council seems to have considered itself a something quite separate and apart from the members generally, its president elected in perpetuity, its members discussing amongst themselves who shall retire and in what order, giving rise to much unseemly bickering, and tending to keep the power in the hands of a few individuals, and which, in the end, tends to formulate a sort of despotic authority which is no longer endurable.

(2) By what right does a council (as a council) take it upon itself to nominate, in a general meeting of the members, certain persons to serve on a committee? By what right does a council seek to interpose between a body of members, who sign a requisition, and the meeting they seek to address? By what right, or upon what principle, does a council offering honours to those who distinguish themselves in the art, constitute themselves judges as well as donors, instead of appealing to a jury of independent persons?

(3) There can be no doubt but that, right or wrong, an immense feeling of dissatisfaction has arisen. It was high time that matters were brought to a crisis, and whether the mode of doing so has been the one best calculated to effect the purpose can only be proved by the results of such action. To dwell upon the past is futile. The enroute of events has placed power in the hands of the opposition; they will, I trust, use it wisely in placing the constitution of the society on a much wider basis; in providing for a constant circulation between council and members; in so arranging, that each year the council shall see a change in its constitution, by the introduction of new energy and fresh ideas in the persons of those members who, being modest and unobtrusive, have not sought for or obtained a position in which their talents and industry could be of service.

(4) The subject of admitting country members has been abundantly discussed by the advocates of the new constitution. It was felt that it must be postponed until the important question which concerned the metropolitan members only was disposed of; this now being the case, the time has come for the consideration of the important step of admitting every member of the society to the right of voting and nominating, quite irrespective of his presence or absence at any particular meeting; and upon this subject there will be little or no difference of opinion.

(5) I firmly believe that the sole motive of those who desire a reform in the society has been to promote its welfare, by raising it to its true position; by helping it to a journal very different to the one which is now presented monthly to its members; by attaching to it "corresponding members," not in England only, but on the Continent and wherever there is anything to be learnt; by enabling it to obtain its information first hand; by enlisting in its favour the sympathies of all who conscientiously practise the honourable occupation of photography; by eliminating from its government all suspicion of favouritism and jealousy; and finally, of enabling the society to take rank as the real centre to which all that is worth knowing or practising in the art of photography shall naturally gravitate. J. R. SAWYER.

[Our correspondent's letter arrived too late for insertion last week. It requires one or two brief notes of comment. As coming from one of the really single-minded and conscientious amongst the requisitionists, it fairly represents the singularly incomplete and mistaken view which honest men can take of very simple and plain facts. Our correspondent is a gentleman who, having joined the society when it has been nearly twenty years in existence, speaks of its having "become" practically an oligarchy, &c. Whatever it is, it was when he joined it. The council *seems*, he says, to have considered itself something quite apart from the members. We, from long personal familiarity of the society and the council, *know* that they considered nothing of the kind. Of course they discussed amongst themselves who ought to retire: that is part of their business, as it is of every council and

board in the kingdom, as no one can know so well as they who is efficient, and who is inefficient; who attends to duty, and who does not. The "bickerings" to which our correspondent refers are in his imagination. We never saw anything approaching to a bickering on the council. They had no power to keep the authority in their own hands, as the society had the power to elect seven new officers every year. The fact that they always accepted the nomination list of the council simply showed that the society at large had full confidence in the council.

The council has assumed no "rights" different from those of the members generally. It has simply had very specific duties; and amongst these was the conservation of the constitution of the society, which was committed to its charge, from wanton, crude tinkering. Where reform was desirable, they knew it could be better and more wisely managed under the advice of some whose experience in the history, vicissitudes, and general working of the society gave their hints value, than under the sole guidance of a committee consisting of persons new to the society, unfamiliar with its history, and ignorant of the special vicissitudes through which the society has passed. And hence they felt it important to suggest that three of the revising committee should be left to their nomination. The crude and narrow rules proposed by the requisitionists certainly gave no indication of a degree of wisdom from which much could be hoped in dealing with other rules. In any case, if "rights" were in question, theirs, as duly elected by the members to official duty, was surely transcendently greater than that of a self-elected junta who did nominate *all* the committee. The council did not interpose between a body of members signing a requisition and the meeting it sought; but when that body sent in an illegal requisition, the council sent a courteous and conciliatory message, offering to facilitate their views without the necessary delay of getting up another requisition in legal form. And when the requisitionists (or a few of them) sent an insulting letter (which they garble in giving to the public eye) and another requisition, the council called a meeting, even although the requisition contained the names of many disqualified from legal action by being in long arrears of subscription, and one name of a person who had never been a member of the society. The council, being the elected representatives of the society, in distributing honours, appoint the gentlemen to judge whom they conceive most capable of forming a correct judgment. They were elected by the society to arrange all such matters. On what principle can members of the council be supposed to be less independent in distributing honours than non-official members?

The utter groundlessness of the statement that a widespread feeling of dissatisfaction prevails is shown in the fact that with all the canvassing and organization used by the requisitionists, but twenty-eight votes were secured, and these, some of them, since regretted. The result, of course, remains to be seen; but it is not hopeful at present.

If any idea of admitting country members to voting powers was originally entertained by the requisitionists, it is clear that they rejected it, as their rules exclude it. It is quite probable that since the question has been so cogently put by the council, and those who agree with the council, that it has been dismissed; and it is more than probable that, thanks to the arguments of the council and the loyal members, such a course will now be forced upon the requisitionists. But in doing this, one of the first things they will be compelled to do will be to rescind or alter the rule which they made such an effort to carry, in which there is not only no provision for country members, but an absolute prohibition to even nominating members of council unless they attend in person to do so, whilst the old rule of the society permitted written nominations without personal attendance. The present meagre character of the society's Journal is due solely to the influence of those members of the council who are now with the opposition. These gentlemen have, out of an honest regard for economy, proposed the abandonment of the Journal, and, failing that, reducing its cost as much as possible. When the new *regime* has acquired a little knowledge of the business of the society, they will better understand the aims and action of the late council. The removal of suspicion of favouritism and jealousy will be a worthy ambition; but, as the new *regime* is initiated under the especial influence of these feelings, a serious purgation must arise before the desired millennium of the society is attained.—Ed.]

#### THE FRENCH EXHIBITION.

SIR,—I have received from the French Photographic Society a circular note requesting me to contribute to their next exhibition. But the request is couched in terms that place the entire

business upon the level of a shopkeepers' speculation. I aim to pay for the space occupied, and pay rather dear, too. How strangely this contrasts with the liberal spirit in which our Photographic Society of London gets up—or perhaps I ought to say used to get up—its exhibitions. We have never demanded payment for the space occupied by our own photographers, and have ever been ready to welcome with outstretched arms the contributions from abroad; and, instead of making our distinguished neighbours pay, we have in spirit, if not in practice, been more ready to pay them. At least, I believe that cases of pictures sent to our exhibitions by foreign exhibitors have always been returned carriage paid, and this courtesy was shown at a time when the society was by no means too flush of cash. I can scarcely imagine a more subtle insult to offer a man like Adam Salomon or Fritz Luckhardt than to tell him he must pay to be allowed to exhibit his pictures in London at the Photographic Society. To do so would be to suggest that the pictures were not good enough to show on their own merits, but must needs be paid for: as if to be allowed to send one's work to an exhibition were such an honour as to be worth paying for; whereas, in fact, the burthen is just on the other shoulder, and it is the photographer who does honour to the society by allowing them to exhibit his work for the instruction of others.

I hope English photographers will consider this matter before they send their pictures abroad, and see if they think, in the vulgar phrase, "the game is worth the candle." I for one do not think it is, and I will have no more of these shabby exhibitions.

I have sent twice to exhibitions of photographs at Paris. On the first occasion my pictures were besieged in the Palais de l'Industrie, and were, I believe, reduced to a fine powder by the German shells. This, perhaps, was no fault of the French Society, but then they might have had the courtesy to write and say that the boys next door had been throwing stones and had broken our pictures, and that they were duly sorry, and so on.

On the occasion of the last exhibition I paid the demand made upon me for space, and at the close of the exhibition I received a note (scarcely polite) that the pictures must be removed on such a day at my own risk and expense, an agent whom I appointed to do this for me not having attended to the business as he should have done. I received in a few days more a peremptory letter stating that if my pictures were not removed at once, they would be sold—to pay expenses!

For the present, the interest which is felt in France in the productions of English photographers may, so far as I am concerned, rest unsatisfied, as I will not exhibit again to any society whose treatment of their friends varies so very much from the polite.—  
Yours truly,  
AN ENGLISH PHOTOGRAPHER.

#### GELATINO-BROMIDE PROCESS.

DEAR SIR,—As the gelatino-bromide process is now occupying so much of the attention of photographers generally, I must beg a small space in which to say a few words on the subject of some comments made by Mr. Sutton on the process, and which appeared in another journal. My attention has been called to the matter several times, and the question asked, has this process really the drawbacks attached to it, as represented by Mr. Sutton? As the same question may arise in the minds of many, and as I believe there are very few who, from actual experience, can answer them satisfactorily, I will, with your kind permission, give my own experience.

I have now, coated, exposed, and developed, some hundreds of them, and the very faults Mr. Sutton places to their account are the very ones, of all dry plates, they are least subject to. In the matter of the fly and dust traps, as he calls the plates whilst drying, they are just subject to the same risks as all other dry plates. As there are now thousands of these prepared without spot or blemish, that may pass for what it is worth.

He then goes on to say, as gelatine is more soluble than collodion, it will not stand the washings of water and hypo. If he saw how I treat them, I think he would have left that unwritten. I have had them in water for hours between the exposure and development, and not a whit the worse for their long immersion.

Now for the blistering, to which he says they have such a strong tendency, and of which I have the greatest horror. I am pleased to say in my hands they are perfectly free: they are, I think, of all dry plates, the most free from that particular defect. They will, however, soon be put to the test, and by this time next week I have no doubt there will have been some hundreds put through the ordeal, as I am receiving orders by nearly every post in anticipation of issue, some asking if I cannot oblige by letting them, as a favour, have the pellicle earlier than the time named,

while from the great delay there has been in getting my plant for the manufacture of it in working order, I am afraid I shall not get any out before the time named.—Your very obedient servant,  
R. KENNETT.

#### CHEMICALS AND MANIPULATIONS.

SIR,—I see in No. 803, January 23rd, 1874, Mr. W. T. Wilkinson lamenting "the want of sensitive chemicals and permanent prints." I have been using the acetate of lead formula recommended by Mr. H. J. Newton in the PHOTOGRAPHIC NEWS, vol. xv., page 382, giving four changes before and four after the lead solution, exclusively for the last twelve months, and some prints have been exposed to the atmosphere during that time, and I have not seen any visible change in them. I think a print more stable washed that way than one that has had eight or ten hours' washing in the regular way, to say nothing about the convenience of it, for you can print, tone, and mount the same day with it.—I am, sir, yours truly,  
E. TREMBATH.

### Proceedings of Societies.

#### MANCHESTER PHOTOGRAPHIC SOCIETY.

THIS Society met on Thursday, the 12th inst., Alfred Brothers, Esq., V.P., F.R.A.S., in the chair.

The minutes of the last meeting were read and confirmed.

The Chairman read the following letter from the Rev. Canon Beechey, M.A., V.P.:—

"MY DEAR MR. ADIN,—I am delighted to be among you once more in any capacity, even though I now appear as a 'caution.' But only think that, after more than thirty years of oxyhydrogen experience, I have had an explosion (the first I have ever known), which might have been a great deal more calamitous than it was.

"I think it may be interesting to our members, and perhaps even salutary to the public, to know how this happened, inasmuch as it resulted from no carelessness, nor any previously-experienced cause, so far as I know.

"Just before leaving Worsley for Hilgay I bought a new bag from Messrs. Macintosh, which they made on purpose for me, and a real beauty I thought it. I kept it rigidly for oxygen, and luckily for me it proved that it was not full of hydrogen, or I cannot tell the consequences! As soon as I got here I had a new pair of jets from Knott, of Liverpool, and beauties they also appeared.

"I only gave two lectures last winter, and on both occasions I found a difficulty in getting sufficient oxygen for more than a comparatively small jet of hydrogen. However, the light was sufficient for my school-room, so I did not investigate the cause.

"This winter, I was about to lecture more. My first lecture was like the former; but having no longer a son to manage my lanterns, I was endeavouring to teach my intelligent gardener, and was determined to get a good light, so we rehearsed in my study! First trial, light as usual! 'What is the reason we cannot get oxygen enough?' I took the jet to pieces; it was quite clear. I blew through the tubes: they were perfectly free. I examined the taps, and took out the plugs; there was no impediment anywhere. It could not be in the bag, for the gas went *into* it quite freely. Well, let us put on more pressure. We had only fifty-six pounds on each bag (as it was for my study, and of course for a small picture), so we put one hundredweight on the oxygen. Then I cautiously thought it was not safe to have *unequal pressure*, even though it was only the supply of oxygen which was deficient. So we added another fifty-six pounds to the hydrogen also, and regulated the supply by the taps. To my surprise and annoyance, whilst the flow of hydrogen was greatly increased, that of the oxygen appeared even less than before.

"My man was trying to get the light. He had turned on only a very moderate jet of hydrogen to begin with, but could not get oxygen enough to ignite the lime with it! He turned on the oxygen tap quite full. The supply appeared to grow less, and soon ceased entirely! In another moment a loud explosion took place, and my oxygen bag burst into a tremendous flame four feet long and from eight to ten inches wide, which would soon have set my room on fire had I not jumped on to the pressure-board, and so squeezed the bag tight at the point of ignition! Fancy how grandly india-rubber would burn in oxygen gas! No sooner was all out, and all safe (for which, I assure you, I felt very grateful) I took up my poor new bag. It had burst, and had burned at the thin edge from the tap about a foot along to the right.

"On opening the slit the cause of the explosion was at once apparent. By some unaccountable accident in the manufacture the india-rubber, which appears to be put in large quantity round

the inner end of the tap, had been squeezed out from its bandages and literally formed a valve thus, over the aperture within the bag.

You see that this would allow the gas to enter freely, but that it closed as it came out, and the more the pressure the tighter it closed. It was not, therefore, difficult to see exactly what had happened. The pressure in the tubes was very small—enough to let the oxygen come in, but so that the greater pressure of the hydrogen forced it in also to mingle with it, and no sooner were the two mingled in right proportion than of course explosion took place.

"Now this explosion was evidently only throughout the length of the india-rubber pipe. This was of large bore and very strong. It fired, and therefore a tolerable charge right into the bag blew in the valve, and by its tremendous flame first burst the bag, and then ignited at the opening, allowing the oxygen to escape through the rupture all the time it was burning. Had it been the hydrogen bag, of course all the ten cubic feet therein would have ignited, and the explosion would have been much more serious; as it was, it blew off the weights by the expansion, and the flame was really something to look at.

"Moral: whenever you find any impediment to the flow of either gas, never go on trying to get a light from them, but turn off your taps at once, disconnect your tubes from the jets, and be sure to get a perfectly free flow of the single gas before you connect again!—Your faithful and loving V.P.,  
"Hilgay Rectory, Downham, Norfolk." ST. VINCENT BEECHEY.

Mr. JOHN BRIER, Jun., read a paper on "The Production of Enlarged Landscape Negatives" (see page 98), and exhibited several prints and negatives in illustration of his remarks.

Mr. FRANKLAND exhibited a number of cameras and other studio apparatus. He said he had a large experience in taking photographs of babies. Sometimes he found great pleasure in taking them; at other times they were a great nuisance. He sometimes thought mothers had conspired against him, and brought all their babies at once. Babies, however, must be taken, there was no mistake about that. It was best, therefore, to lay one's self out for that class of work; for, if they were well taken, the result was more business from older subjects. The baby shutter was of very great value to him; it enabled him to engage the attention of the child with a toy or other object in one hand, while the other was free to work the shutter. He obtained the idea of the shutter from Mr. Blanchard. He (Mr. Frankland) exhibited two of the shutters—one vertical, the other horizontal; also a camera adapted for taking one, two, or four negatives, and a touching desk with light, shade, and hand-magnifier.

Mr. HAYWOOD said the present was one of the most interesting meetings it had been his good fortune to attend. He complimented Mr. Brier on the reading of his first paper before that or any society, and said it did him very considerable credit. He pointed to Mr. Brier as a good example for many members who took no active part at the meetings to copy. He also complimented Mr. Frankland on his most interesting display of apparatus. A written description, with drawings, was much less instructive than an actual inspection of such articles as Mr. Frankland had kindly brought a distance of twenty-seven miles to show to the meeting, and he was quite sure the meeting would fully appreciate the efforts of Messrs. Brier and Frankland.

Mr. NOTON exhibited a new form of lantern for the lime light. He said he had taken a hint from the sciopticon, as the form of the lantern would at once show. The body was made out of an Australian beef can, the front part carrying the lens out of a small ditto, and the chimney out of a preserved milk tin. The lantern, unlike the sciopticon, was, he said, a breech-loader, for the condensers were inserted from the back.

Mr. Noton's lantern had a most compact appearance, and served to show how articles that many persons would consider worthless could be transformed into good-looking and efficient apparatus.

The meeting, which was largely attended, was then adjourned.

## Talk in the Studio.

**HONORARY MEMBERSHIPS.**—The Vienna Photographic Society have (in approbation of his photographic improvement and his most excellent and artistic performances) made Mr H. P. Robinson an honorary member. M. Angerer (Austria), M. Davanne (France), and Dr. Vogel (Prussia) were made honorary members at the same time.

**MATT VARNISH.**—We have received from Mr. Barratt, of Torquay, an example of a matt varnish which he has recently perfected. So far as we have been able to test it, the result is excellent. It gives a very finely grained surface, presenting a tooth, without making the negative or transparency to which it is applied in any degree opaque, whilst it takes lead-pencil touching very kindly, and permits the finest possible form of working. It seems to give an exceedingly hard protective surface. We think it will just meet the wants of many photographers.

**PROPOSED TAX ON PHOTOGRAPHS.**—The *Daily News*, giving a burlesque account of reasons which induced Mr. Gladstone to dissolve Parliament, states it as the result of a thorough disagreement as to the mode of disposing of the surplus, and a still greater disagreement as to the new taxes to be imposed in case of giving up the income tax, no less than two members having agreed to impose a tax on photographs. Here is an extract from the startling account:—"Lord Granville, holding in his hand a petition from 75,000 authors, artists, students, and invalids, proposed to place a prohibitive tax on barrel-organs; but Mr. Lowe strongly objected to any interference with these instruments; remarked that but for the charms of music, which were of proverbial efficacy, he could never get into the proper mood in which to receive deputations; and added that his friend Mr. Ayrton, if he had had a voice in the Cabinet, would have said the same thing. Mr. Forster's proposal to lay a tax on novels written by ladies (excepting those of George Eliot) and on imported French dramas met with no better fate; for Mr. Gladstone bluntly declined to make his Budget an instrument of moral culture, and spoke with some bitterness about the results of Lord Aberdare's shutting up of the public-houses. Two of the Ministers had, however, so far agreed as to recommend a tax on photographs, as an article which was at once cheap, a luxury, and of universal consumption; but those members of the Cabinet who had not been introduced into burlesque groups and put in the booksellers' windows consider that the poor photographer should not be harassed. A great number of proposals of this sort were brought forward only to be negated, until the discussion got very warm indeed, Mr. Gladstone observing that the preparation of the Budget was his own business, and that he would not be interfered with."

## To Correspondents.

**ALEX. HENDERSON.**—Various plans are adopted by different photo-collotype printers. The plan adopted by Albert is to use a plate of thick glass—which may be plain or ground—for the basis of the gelatine printing surface, the sensitive gelatine being exposed at the back first, to harden it and give firmness to its hold on the glass. 2. Various kinds of inking rollers have been tried. Those of leather, like lithographic rollers, are, we believe, found best. The composition of glue and treacle does not answer well. 3. The preparation of the ink for different subjects is a point requiring much experience for success. Varnish, and sometimes a little turpentine, are used, we believe. 4. The ink is similar to lithographic ink, and is generally purchased ready for use of the manufacturers. Various makers have, probably, different recipes.

**DEPTFORD.**—Distemper colouring is not suitable for photographs, as, being quite opaque, it covers up the photograph, and the finished picture depends entirely on the skill of the artist for any likeness it may retain. Distemper painting consists in using body colour; that is, colour mixed with opaque white. A little may be judiciously used in covering up black shadows; but, as a rule, it should be avoided in colouring photographs.

**ALFRED STANTON.**—It is difficult to say which is the best mode of enlarging from a card portrait to life-size, as fine results may be produced by many processes when the manipulator is master of the working. If several copies are required, we should produce an enlarged negative by one of the methods recently described in our pages. If one or two copies only were required, we should use the collodion transfer process, also recently described in our pages and in our last YEAR-BOOK. The price of Captain Abney's book is 2s. 6d.

**G. SEBRIGHT.**—Being an old subscriber, you have doubtless read the various articles and discussions on the subject of enlarging and reproducing negatives which have recently appeared in our pages, from which you will glean much more information than we can give you in this column. If you have not had practice in this direction, and require at once negatives, to get on with commercial work, we should recommend you to get a few negatives enlarged and vignetted from some one who undertakes such work for the trade, such as the Autotype Company, Mr. Edwards, or Mr. Croughton. Should you wish to undertake the work yourself, we should recommend you to print your transparency on a dry plate, if you are familiar with a dry process, or on collodio-chloride, which is one of the most simple plans, and vignette it as you would a print. Then produce your enlarged negative from the transparency so obtained. You will find many valuable hints in the little work, "Photography in Four Lessons," just issued by Mr. Solomon.

**DARK.**—The photographs to which you refer are fine copies of Thorwaldsen's well-known bas-reliefs, and are photographed either from the originals or from fine casts. They are produced on the Continent, and are published in this country by Marion and Co., of Soho Square. They are doubtless copyright.

**T. S. Z.**—Your landscape lens will answer the purpose very well. Use the largest stop which will give definition to the edges of the group. You must ascertain that at the time by examining the focus on the ground glass. An ordinary fifteen or twenty-grain developer will answer.

**J. & G. R.**—We have no more information on the subject of Mr. Bigelow's studio than is given in his own description. His aim is to illustrate certain principles of lighting rather than to describe a precise size and plan of studio for everyone to adhere to.

**T. STOKOE.**—Our publisher can supply the YEAR-BOOK for 1873. The gold solution to which you refer is manifestly a stock solution to be added to water in the proportion of one ounce to four or five of water.

**R. F. J.**—We regret your decision, and the cause; but we cannot, unfortunately, discuss it in these pages.

**A. HARRISON.**—Thanks. We shall publish the communication shortly.

**G. F. T.**—The "requisition" was got up by one or two persons, and the signatures were obtained by hard canvassing, and bearing the brunt of many refusals. One gentleman who refused informs us that he was urged with very plausible arguments, which he fortunately withstood.

**L. O.**—Dissolve twenty grains of bichloride of mercury in an ounce of water, and place a good vigorous positive into this solution, and leave it there until the image is quite white. Then wash well.

**G. O.**—The lighting is very good, and the portraiture generally is good. The "Rembrandt" style generally includes strong lights and deep shadows, but these should be harmonized by perfect gradation of half-tone. Some persons prefer the lights somewhat stronger, or more vivid, than is found in your specimens; but there is great risk, in such case, of producing hardness.

**G. MACKIE.**—You will find the lens you have (No. 1) will answer very well with a moderate stop. If you purchase, we should prefer No. 3.

**AN IRRECONCILABLE** contests Mr. Woodbury's views on the subject of the award of medals, which, he thinks, should be "given to the best men, in the society or out of the society; in the council or out of it." But, he adds, "it ought to be an absolute condition that no medal should be awarded to anything which has been patented. If a man, having made an invention, patents it, to keep it to himself, he certainly ought not to expect to receive special honour for taking care of number one. He may have a perfect right to the pudding, but he should be content without the praise." As we have before said, any discussion on medals is premature. It will be quite time to discuss who shall receive them when it is certain that anything of the kind will be distributed.

**ASHBY ZOUCH.**—We do not know any style under the specific name of the "New Berlin Card," nor have we heard of any special novelty in portraiture which has recently been produced in Berlin.

**ANTOINETTE.**—A process was proposed in which a print, dipped in dilute acid, and then placed upon a plate of zinc, would, by the galvanic action set up between the two metals, commence an etching action. We have never heard of the process being put to any practical use. 2. We cannot with certainty tell you whether the Autotype Company now permit visitors to see all their operations. We believe that, on application, you will obtain permission to see the ordinary operations of carbon printing. Their negative enlarging process involves some secrets which they will not, of course, exhibit to visitors.

**M. L. D.**—See article on the subject, and other letters.

**ERRATA.**—Mr. Johnson, writing to us from Paris, mentions that

M. Walery is now resident in Paris, not in Marseilles.

**CLEMENT ROGERS.**—Thanks: we will make an extract.

Several Correspondents in our next.

## The Photographic News, March 6, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### PHOTOGRAPHY IN THE THEATRE—WASHING SILVER PRINTS— EDUCATION OF PHOTOGRAPHERS.

*Photography in the Theatre.*—It is now many years ago since the attempt was made in Paris to photograph a tableau on the stage, in some brilliant spectacular piece, *La Beche au Bois*, if we remember rightly. A most striking and brilliant scene was chosen, with the dramatis personæ carefully posed, and illuminated as vividly as possible, and a representation of the *coup d'œil* was sought to be secured in the camera. The experiment failed, as one might have foreseen, and recourse was then had to a stage and scenery devised especially for the purpose of photography, and which was illuminated by daylight. A result of some kind might no doubt have been secured if the stage and accessories had been illuminated for the time being with magnesium powder and other brilliant fires; but then, as play-goers know very well, when they light up at the wings at the tag end of some brilliant fairy spectacle or transformation scene, it usually spoils the whole effect, and, while imparting quite a garish look to the artistes and their drapery, show up the tinsel and tawdriness of the scenery in their full aspect. Therefore, although pictures could doubtless be secured under such circumstances, they would be scarcely worth having, after all, the colours and contrasts appearing quite different under the effect of these strong lights to what they are before the foot-lights. Recently, however, oxyhydrogen illumination has become more common in our theatres, creating quite a revolution in some respects. In the brilliant scenes of a burlesque or extravaganza at the big theatres, as many as ten or a dozen oxyhydrogen lamps are employed to illuminate the scene, yielding a light of the most vivid brightness. It is the custom, too, at first-class houses, where *spectacle* is particularly attended to—as, for instance, at the Gaiety Theatre—to choose the colours for costumes, not as they look best by daylight or gaslight, but when under the influence of the most powerful oxyhydrogen flame, so that the tints, whether they harmonise or not under ordinary circumstances, shall do so most completely before the audience when properly illuminated. It would be interesting, therefore, to see whether, with the aid of this stronger illumination, and with scenery and costumes suited to the more brilliant lighting up, a camera picture could not be secured of the pretty tableaux and pleasant landscapes often presented to the eye in Vesta's temple. Whether the scenic artist and costumier could not again learn something from the photographic results thus obtained is also a question, either by comparing the picture with photographs from nature, or studying the effects of light and shade thus registered. A very ludicrous incident connected with the photographing of scenery came under our notice a short time back. The proprietor of some pleasure gardens near London erected at the one end of his grounds, on the further side of a sheet of water, a city of palaces on cardboard, or rather on canvas, after the manner of the old Surrey Gardens, which some of our readers may remember. The effect of distance was very cleverly portrayed, and, as the public could not approach very near because of the water, the illusion was most complete, especially towards twilight. The proprietor was not a little proud of his castles in the air, and, fearing that the drenching rains of our uncertain climate might "dissolve, and leave not a rack behind," of the beautiful structure, he resolved forthwith to have a photograph taken. Whether he secured a portraitist or landscape photographer to do the work we are not aware, but any way, all exertions of the operator failed to give a satisfactory rendering in the camera. The skylight of the scene, which to the eye was scarcely perceptible, so cunningly had it been painted to match the atmosphere beyond, came out in the photo-

graph as a sharply defined outline, giving one the notion that if man might be imposed upon, the camera, at any rate, was not. The photograph, indeed, clearly proved the whole to be a sham and nothing more.

*Washing Silver Prints.*—Whatever may be said regarding the fading of silver prints, it is very certain that the leaving of free hyposulphite in the pictures, after fixing and washing, is due simply to sheer carelessness. The testing for hyposulphite by means of starch faintly coloured with iodine is a most simple matter, and, moreover, one of the most delicate tests that can be employed. Pictures to be examined are simply steeped in a small proportion of hot distilled water for a short time, and this water, poured into a test-tube containing iodide of starch, will bleach the latter in the case of hyposulphite being present. Nothing removes hyposulphite so readily as rinsing in warm rain or distilled water, and it is a good plan to effect the last washing in this way, for if the prints have been soaking, no matter how long, in very hard and very cold spring water, the chances are that the noxious salt has not all been altogether removed from the body of the paper. Those who desire to know how to make a quantitative examination of hyposulphite in paper or cardboard should read Dr. Vogel's capital article on the subject in our last YEAR-BOOK.

*Education of Photographers.*—It is a pity there is no opportunity afforded to practical photographers to obtain a sound, scientific teaching of the principles upon which their art is based. Your professional photographer at the present day is either a very capable artist, who has taken to photography because he finds he can realise his ideas more quickly and quite as efficiently by the aid of the camera, or one who has previously been an assistant, and has become a master. The chances are that the former will always remain a good artist and an indifferent photographer, while the latter will work with clearness and delicacy, and his failing be a want of artistic knowledge. Of course there are many, now-a-days, who have very nearly attained to perfection, both in the artistic and technical branches of the art, but these are in the minority, and we do not speak of them. To give the artist a greater knowledge of chemical and technical matters connected with photography, and to impart to the practised manipulator some idea of art, are things equally desirable; and to do this properly we are in need of some institution or association. Lectures alone on the subject would not suffice, but demonstration and personal instruction are required. We cannot think that the time is very far distant when we shall have such a want as this satisfied.

### ON THE USE OF THE CAMERA.

BY A. S. SOUTHWORTH.\*

I HEARD a gentleman speak of receiving a card of the name of the sitter. When my sitters come into the room I want to be acquainted with them. A card with their names on it would not suit me at all. I would take them by the hand, and relieve them of their drapery that they wish to lay off; make them comfortable; point them to the room where they can take care of and dress themselves as appropriately as they please; then I ask them into the light-room. I do not always leave them in the dark. I bring them into the light-room that their eyes may be accustomed to the light in which they are going to sit. You go around into the room, and show them the objects of interest; view their faces in the different lights, and get familiar with their countenances, and endeavour to call out their ideas.

Remember that expression is everything in a photograph. All else—the hair, jewellery, lace-work, drapery of dress, and attitude—are only aids to expression. It must at least be comfortable, and ought to be amiable. It ought also to be sensible, spirited, and dignified, and usually, with care

\* Condensed from a paper read before the N.P.A., U.S.

and patience, may be so. A little practice, with a friend to prompt, before a mirror, will save time, and very likely be the means of much increasing the satisfaction of those for whom the likeness is made.

The hair in its arrangement should assist the proportions of the head. If the head is too long and the face thin, the hair should widen and round the features. If the cheek-bones are too high and too broad, the breadth of the head should fall lower down, so as not to exaggerate features already too large. The hair may be smooth or lay evenly, but should never be sleeked or matted down; and the practice of shaving the forehead or pulling out the hair is altogether too barefaced for a lady. It should be arranged in curves, waves, or curls, avoiding angles and horn-shaped protuberances. Caps, turbans, lace, and jewellery, should conform to the same rules in aiding the general contour towards good proportions.

All lace-work should be light and thin, never massy, though it may be white or black to suit the occasion. Flowing curls, for misses, over a low-necked dress, or for young ladies with handsome outlines of neck and shoulders, are picturesque and pleasing, but thin necks and projecting collar-bones require high dresses with lace, whether in fashion or not. The same remarks apply to arms and hands. If not filled well, with good outlines, let them be appropriately covered in a picture. Simple jewellery may be taken, but if heavy or massy it is not admissible, except for fancy pictures. If the figure is good, the fashion of the dress should show all handsome lines or curves, and hide all that are not so. If the figure is not well proportioned, the fashion of the dress should make it appear so as nearly as possible. It is ridiculously absurd for all females to adopt the same fashion; one exact size and pattern for all would hardly be more so. Whatever the fabric selected, avoid large figures or broad stripes.

Figures of the same material and colour—as watered, striped, or figured dark silks, or very narrow-striped light silks—are well suited to the photograph.

Dark colours are generally more appropriate than light. Fair complexions may, if the figure is represented on a small scale. Remember that positive red, orange, yellow, or green, are the same as black, or nearly so; and violet, purple, and blue are nearly the same as white, and arrange your costume accordingly. Rich figured shawls or scarves and dresses usually show well in a picture. Full promenade, carriage, or riding dresses look well as such, although not suited for a simple likeness.

Infants too young to sit upright should be taken in their long frocks, but when a little older their feet need not be covered; but the whole figure may be prettily taken if they can be kept quiet four or five seconds. As a good rule, let the frock be very low in the neck, with short waist, not tight, yet fitting the form, reaching to the foot; the sleeves very short and loose, ornamented with narrow lace. The skirt should be of woollen fabric, not too full, reaching about half-way from the knee to the ankle, and worked, figured, or scalloped around the bottom. No other underclothing should be worn, except of the thinnest and most pliable material.

If the child is taken half-reclining, the bottom of the dress can easily be arranged to show parts of the bottom of the skirts, and the feet and ankles, and all be in good keeping and taste. The colour of the frock may be pink, drab, blue, or any colour which will show light in the picture.

Especially should it be permanently impressed upon the "sitter" for a photograph that the artist has in reality no control over the actual expression of the subject, which is the important part of a photographic likeness. Having disciplined the features of the face until controllable, select an hour for sitting when you may be in your best mental, as well as physical, condition. Arrange dress and drapery in your most tasteful and graceful manner, so that it shall be at least to your own satisfaction. A

figure laced to suffocation, a foot aching under the pressure of a too diminutive shoe, or the hair drawn and twisted so tightly as almost to lift its wearer from the floor, thus imparting stiffness and awkwardness to expression, even in repose, are but a few of the obstacles with which it will be useless for an artist, however patient or earnest he may be, to contend.

The hour of departure on a tour or travel, a few hasty moments snatched from a shopping excursion in town, or between hurried morning calls and dinner, will not be likely to find one in a sufficiently fresh and quiet mood to yield to the hints the artist may desire to throw out expressly for the sitter's benefit. It has been said that "the most terrible enemy the photographer has to contend with is human vanity." This is in a great degree true. The repeated trials which the artist finds it necessary to make to avoid time's rude finger-marks, to overcome the rigidity, languor, or sadness of expression which diseases or affliction may have produced, are among his difficulties and discouragements. Let not these be increased by the infelicities of time or condition above referred to. On your own account, as well as for the sake of those who will value a correct portrait of yourself, choose the most favourable opportunity, as already suggested, and afford the artist ample time, without haste or nervousness, for his labour.

Next, select the artist in whom you have confidence, and whose efforts are to merit and sustain a high reputation; attend to his suggestions, and feel at home in his rooms, that you may relieve him from all embarrassment, and put him equally at ease in your presence. If you have ideas of your own as to the light and shade of view of the face, suggest freely, and then submit all to him. If qualified for his business he will soon be able to transfer your likeness so as to render prominent the best features, and at the same time conceal or diminish those having least beauty. Aid cheerfully his exertions; and if, with the best efforts of both artist and subject, the result is a failure, charge it not upon his demerits, nor be discouraged, but try again, and you will thus eventually be successful.

Again, have confidence in art itself. There is far more danger of undervaluing than over-rating it. It may not, like painting and sculpture, be susceptible of the expression of feelings and emotions which have been awakened in the mind of the artist, and more nearly realized in his own conceptions. Though it be not to his inner fancy in the creation of scenes, and characters, and forms, which might have existed in a state of higher perfection and rarer intellectual refinement, yet the genius and spirit of poetry must possess the artist, so that he can ever elevate his characters in portraiture far above common nature. He must have power to embody the beauties and perfections of his subjects, and at the same time make clear resemblance and identity. He must keep ideality uppermost, and thus infuse it into the mind of the beholder, so that he be not degraded to a servile copyist, and his art to a mere resemblance. And although, as has been already hinted, he who in painting and sculpture can work to his own ideal has a wider range in portraiture, and can bring colours as well as forms of nature to his aid, yet in the nice production of light and shade, which is the perfection of modelling, the photograph will be found to surpass the artist's best efforts; being capable of representing independently action, expression, and character, to a great extent; and in some instances it approaches very nearly, if it does not equal, these higher branches; thus developing beauty in grace of motion, and in repose, which is the first object and the supreme law of all art.

[Mr. Southworth then proceeded to pose the President, with a running comment on various effects, and then proceeded]:

Now I want to go twenty-four feet from the sitter, and I want to lower the instrument one foot. I do not say you can have this position always. I want the largest

lens that you can possibly give me, or that I can get, to take his picture twenty-four feet off; that is, to make it the size of common cartes. I do not want to be any nearer. I mean those large heads on the common cartes, called John Bull cartes, common cartes, common carte size, large heads. Now I do not want to be less than twenty-four feet off. I want the largest lens that I can get to properly focus for that size. Your lens should be at least no less than five inches in diameter. Now my friend Fitzgibbon, of St. Louis, suggested a very nice way of shortening the time, but now I want to make it just a little bit shorter. Instead of using your instrument diaphragmed at all, use it entirely open without any stop, and that will shorten your time, and where it takes thirty seconds the old way, it will now take sixteen. I will make the same in ten, and have the eyes as well defined as you can ask. If there are spots or blotches, you have to touch them out on the negative. You will thus have a softer picture than you can make by retouching, for to save your lives you cannot touch it without hurting it, and men who are making good pictures do the same thing. I do not say if there is any defect that I would not put a piece of soft prepared chalk on, but I say, let it alone. As to the shadows, you cannot touch a shadow without injury. You must place your picture so as to have a good light upon it without shadow and without retouching.

Before I begin to raise my camera, I have said to my sitter, Now there are some things I would like to have you not think of. I cannot help it when they are sitting for a picture, and after I think I am ready for it, I will direct them as to the line of vision. You will please to look at that point if you want the picture to be looking at you, and I must make it so that it falls directly on that line on the edge of the tube or over it, and I want you to look as though you were looking ten miles out at sea. You can open and shut the eyes with the most perfect freedom. You must give a light in which they will not blink. I make it as comfortable as I can, and pay attention to that point while I am taking the picture. The eye must be used at its longest range. You must tell them to look just as far as they can, and let them practise on that look, and you will have it right in the picture. You will not get it cross-eyed. One half the pictures are thus made. The eyes are this way and that way. They are just cross-eyed. Now, if a person is cross-eyed, he never should be drawn so to to that extent. In some of those larger pictures, the eyes are looking at you as if you were only eight feet distant. Now, what is that for expression? It is dead. You cannot wake any life in it. The expression is not good for anything; the eye is not good for anything.

I say, then, with regard to the direction of the eye and the opening and shutting of it, it should be perfectly natural. Now I have arranged the light. I have a sky-light that is pretty high. I cannot have too much room. I have just enough light, so that the sitter can open and shut his eyes easily without blinking.

So much for the arrangement of the light. A single word now should be said with regard to reflected light. Having arranged the light so as to give the shadows the diffused light and shadows as I want them, then I want to look out for this little point, and that is, to the light in the eye; and if you get two points, it will be bad, but if you get one, and this reflects the light, why it looks like one of those that has a film growing over it. The eye is dead. The first thing is to get a good eye, and more than that, the eye must be so made in addition that it will look like a little star, but one light.

I repeat, then, have your lenses as large as your tubes can be; make your pictures as far off as you can get the camera, twenty-four feet distant; with the smaller cartes, get a little nearer, or go further off, and you will find that you will make your picture soft. You will not need to retouch. You will have a good effect where you have this softness; you will have light where you have

black, or the kind of blacks you have now. Nearly all of the so-called Rembrandts—I speak of them so as to call your attention to that class—certainly one-third of all there are—indeed, nine-tenths of those made in the Rembrandt style—are not looking as I have described. Take it while the light is run into the shade; on that side of the face there is not one bit of that black or hardness on the face. It is warmed up with reflected light and with colour. This is terrible; it is terrible to the artist; it is not true; it has simply been quackery from beginning to end, and the worst kind of quackery, to take a person's face with the shadow next to you; it is all proper; the warmth and the shadow are there, so when you look at it you will understand it. You want to make the picture so that every time you take it up you will see new beauties in it, and so you will love to turn over an album of such pictures, every single day to examine the effect of fine photographing, and I tell you it is done a great many times, by a great many artists constantly, and by some constantly, but it is not done by true artists at all. You will excuse me, I am only talking for the very highest reach of our art, but you will tell me that I have aimed a little above it. I did not, but never mind the aim; you must aim high, and you will not be down there long; you will be coming up, and if you never get to the top, you will have a feeling that you are making the very best effort, and perhaps, if you live long enough, you will reach it.

## THE DEVELOPER.

BY B. P. OREENE.\*

I HAVE tried nearly all the dodges of using other substances in connection with protosulphate of iron—such as sugar, rock candy, epsom salts, gelatine, double salts of iron and ammonia, &c.—but have always fallen back on simple protosulphate of iron and acetic acid. I have come to the conclusion that other things are only an extra expense, and of no use only to retard the action of the iron; that the same results can be obtained by using a weaker developer, and save the cost of the other ingredients added as retarders.

My formula for preparing the developer is as follows:—

### *Stock Solution.*

Protosulphate of iron (pulv.)	...	1 pound
Warm water	... ..	2 quarts

For every day's use take eight ounces of stock solution, and three ounces of acetic acid; filter into a quart bottle, and fill up with water, making it in strength two ounces of iron to the quart.

This is the strength I prefer for ordinary purposes. Sometimes you may require it stronger or weaker; that you can vary to suit your work in hand. The shorter the exposure the stronger you want your developer; for that reason it is a good plan to have a bottle of developer in your dark-room, the full strength of the stock solution, with acetic acid added, three ounces to every eight ounces of stock solution.

The method of using will depend very much on the subject in hand; as a general thing, the stiller you hold the plate, and keep it covered with the developer, the better will be the result. If you see the image is coming out too thin in the high-lights, rock the plate so that the developer will wash out the silver in the shadows and deposit it on the high lights; but if it shows too much contrast in light and shade, hold as still as possible, so as to retain all the silver in the shadows that is possible. For solar negatives I should flow the developer freely, so as to wash off all the surplus silver from the plate; then hold still, and let the image come out fine and even; I never use any alcohol if I can possibly help it. I prefer to work over my bath, and free it from the alcohol, than to try to work a bath that you are compelled to use alcohol in the developer with.

\* Read before the Photographic Institute of Chicago.

In landscape work, I always carry a saturated solution with the acid added, and reduce as I want to use it. I have two reasons for this: 1st, it is less bulky, and lighter to carry; 2nd, we are compelled to vary the strength more in out-door work than you are in gallery work. Sometimes—for instantaneous work, and very poorly lighted interiors—I use the full strength of the stock-solution. Also, in the woods, where the foliage is very dense, you are compelled to use a strong developer to obtain detail, while, on the other hand, if it is pretty much all light, I use a very weak developer. The stronger you use the developer, the more detail you will get, while the weaker, the more contrast.

I do not wish to be understood to say that strong developer makes the best work, for the quicker the development, the coarser will be the deposit of silver. Therefore use your developer as weak as you can, and obtain the proper amount of detail.

### NEWS FROM THE SUN.

BY DR. SCHNAUSS.\*

DAME NATURE has established her great chemical laboratory, so far as we inhabitants of the earth are concerned, in the sun. Of this we have convinced ourselves by means of spectrum analysis. The sun is, in fact, a terrific furnace, where Dame Nature is constantly heating retorts, flasks, and crucibles on a gigantic scale. It matters little to her when a gasometer bursts and a glowing flame of hydrogen spurts into the air some twenty thousand miles or so; on the contrary, these explosions, bringing about certain decompositions and combinations, are just the sources of the sun's warmth, which is so indispensable to us mortals.

Despite the respectable distance of the sun from the earth (about ninety-one millions of miles), we know, thanks to the perfection of the optical and chemical means at our disposal, a good deal about the various phenomena that occur upon its surface. Now we photographers, although not actually belonging to the sect of sun or fire worshippers, have more real cause than most other men to hold the luminary in grateful remembrance, and ought, therefore, to make ourselves acquainted with its doings so much as it is in our power to do. We shall pass over what our readers have learnt long ago from old geographical and astronomical books, and will only remind them that we—or, rather, the earth—enjoy the honour of being descended from the sun. Since the parting of Mother Earth, it may be for ever, from the sun, she has gradually become cooler, and thus it has become possible for us puny creatures—and, in fact, everything that crawls and flies and grows—to exist and live without being turned into cinders. And the few million years that have elapsed the sun has not allowed to pass by uselessly, but, on the contrary, the time has been employed for the creation and cultivation of plants and trees, designed, in future generations, to afford provision for latent warmth, so that material may be forthcoming for their railways and manufactories; for without coal these could not be thought of, and this, it must be borne in mind, is a product of the sun's warmth and sun's light for hundreds of thousands of years.

We find ourselves here on earth, then, with an agreeable and cool temperature, whilst our ancestor the sun still glows with revolutionary fire, affording us a proof that permanent revolutions even are of some good, provided always that they are kept at a respectful distance. We enjoy only the good, while the sun itself renders it impossible for any living animal to exist upon its surface with a glowing temperature of about 27,709° Centigrade. An oxy-hydrogen blast flame would be quite cool in comparison.

The sun is, moreover, wrapped up in three envelopes, which we, according to our way of thinking, term atmospheres. The uppermost one is called the crown, or corona;

under this lies the atmosphere of colours, or chromosphere, which gives the strongest illuminating power; and the envelope lying round the sun itself is termed the photosphere. These three atmospheres are in a constant state of great agitation, the most violent storms rushing to and fro everywhere. Here is a capital description, given by a scientific man, of these phenomena:—

“In the stupendous sea of glowing vapour constituting the surface of the sun, there are founts continually, now here, now there, fountains of glowing hydrogen, bigger in diameter than the whole of our earth; they are thrown up in a glowing mass, to a height equal very nearly to the distance that our moon is from the earth. These immeasurable masses of glowing matter, which could sweep away the earth as easily as a steam of water carries away a cork upon its surface, then sink down in the sea of vapour, and give rise to circling waves upon the luminous surface many thousand miles in diameter. There is a raging storm of crude matter going on upon the sun, a wanton contest of glowing bodies, of which no living man dreamed before the luminary had been examined by means of the spectrum. And it may be anticipated that when once the energy of that Titan is exhausted, then the source of life of us poor earthly pigmies will be sealed.”

The well-known spots on the sun, which may occasionally be seen by the naked eye upon the sun's disc when the latter is covered by a translucent cloud, and which are observed to progress slowly and uniformly (re-appearing in the course of some weeks or months, and thus affording a means of calculating the time of revolution and locality of the equator of the sun) these spots are, according to the recent investigations of Zollner, in a measure condensations of portions of the gaseous atmosphere of the sun, similar to the slag in a furnace. Many of these spots have a diameter of more than a million miles.

The so-called protuberances of the sun—which, especially in eclipses of the sun, are seen together with the corona, and have so often been photographed—are the flaming pillars of burning hydrogen of which we have just spoken. Besides these phenomena, the spectroscope has proved to us that a number of elements exist in the sun's atmosphere which also exist in the earth, such as iron, zinc, nickel, copper, manganese, calcium, sodium, and oxygen. All these exist either in a glowing vaporous condition, or in a burning state. Our dearly loved gold and silver have not as yet been detected among all the other elements in the sun, but we hope, as our knowledge increases, and our chemical and optical means of investigation attain to even greater perfection, that we may get to know many things new to us going on upon the sun, although at the present day actually there may be nothing new under the sun.

### REVERSED NEGATIVES BY THE POWDER PROCESS.

BY C. H. JACOBI.\*

In mechanical printing a reversed negative is essential. This may be obtained by placing a reflector in front of the lens, by producing the image in the camera on the reversed side of the plate, or by stripping the collodion picture from an ordinary negative by means of gelatine and leather collodion, the negative in this case, however, not being varnished previously. To strip off a varnished film from the glass is quite a conjuring trick, which fails ninety times in a hundred, and, therefore, in the case of a finished negative, the only way is to reproduce it in a camera, or by contact printing. In both these cases a positive is produced in the first instance, from which the negative is afterwards derived. I usually obtain the dia-positive in the camera, and then secure a negative from this on iodide of silver or collodio-chloride plate by means of contact printing.

In this way, however, it is difficult to produce so soft and harmonious a negative as the original, and for this

\* *Photographisches Archiv.*

\* *Photographisches Correspondenz.*

reason I tried another method of reproduction—the powder process—which yields a much finer grain, and necessitates no positive. In the first place, I obtained, by the advice of Dr. Liesegang, some very fine chalk (Conté Kreide No. 2), which I reduced to an extremely fine powder, and found answer my purpose very well. A second supply of the same material was, however, of a much greener tone, and this held back the light and gave a harder negative. As in Lichtdruck and mechanical printing, with half-tone, a soft negative is very essential, I tried if a better powder could not be obtained from graphite, and found that when finely levigated this gave great promise, and I now prefer it to all other powders for the special purpose required.

The sensitive mixture for producing the image which I employ is no great secret, for many formulæ have been published; I usually mix in the following proportions—viz :—

Gum arabic	...	...	...	...	1 part
Water	...	...	...	...	40 parts
Sugar	...	...	...	...	2 "
Bichromate of potash solution (ten per cent. in water)...	...	...	...	...	7½ "
Solution of honey (one part honey, and two parts water)	...	...	...	...	1½ "

The temperature and moisture of the air must be taken into consideration in making the mixture, and the proportions of sugar and honey varied accordingly. The mixture is applied warm to a patent plate glass (which has also been warmed) being of a uniform and thin consistence; it is dried rapidly, and then exposed to light under a negative which has also been slightly heated.

After exposure, the plate is taken from the frame and developed by means of a brush and the developing powder. Some skill is necessary to treat a large plate successfully with powder, so that no dark spots are produced. Care must be exercised to see that the dark room is not in a damp state, as otherwise smeary patches will inevitably be produced. When the dusting is finished, normal collodion is poured over the same, and before the film is perfectly dry it is washed with clean water, and subsequently varnished.

The main point in the powder process is to have the original negative upon as smooth and even a glass plate as possible—such, for instance as patent plate—so that no sharpness may be lost. And in reference to negative, I may state that year long experience has taught me to prefer soda fixing to cyanide of potassium. A large portion of beautiful plates which I have transferred by means of gelatine have become so dense, although stored in the dark, as to become quite unfit for printing.

ALBUMENIZED PAPER.\*

OF the many things which photographers make use of in their daily work, there is none so little cared for in photographic journals as albumenized paper; and as it is one which plays a by no means unimportant rôle in photographic operations, these few remarks may not be out of place. We do not propose to go into the matter of manufacture of the material, so much as to regard the subject from the consumer's point of view, and to indicate certain principles by which one should be guided in regard to the material.

In the manufacture of any article, two points must especially be borne in mind, viz., either it is a product created out of raw material, or something due to the further elaboration of such product. It is to the latter class that the preparation of albumenized paper belongs, for this material is due to the further treatment of a simple product—paper—with albumen; and it is to the circumstance that the finished material always depends upon the quality

of the first product employed that so much variation in its nature is due. Even if an albumenizer of reputation exercise great care and attention in the preparation of the albumenized material, he is still dependent in a great measure upon the quality of the original paper; and it is, unfortunately, on account of imperfections in the latter—such as impurity of the pulp, unevenness in sizing, and in the strength and pressing of the paper—that the defects in albumenized paper are mostly due. As, notwithstanding recent improvement, it has been impossible for manufacturers to make paper, as regards purity, sizing, and strength, perfectly uniform in every sheet, and there is no probability of such a desideratum, it is idle to look for absolute perfection in a material which it is out of the power of the albumenizer to control, for he, of course, cannot set aside the defects which already exist, and cannot be held responsible for them.

Most of the well-known albumenizers have succeeded only after years of experience in producing a uniformly good product, and are always exerting themselves towards supplying a faultless albumenized material—a step necessitated, in a great measure, by the competition existing between manufacturers. There is, perhaps, no other article employed in photography which, in its manufacture, is connected with so many difficulties as albumenized paper; and this, it should be remembered, served for the printing of photographic results all the world over, as being frequently inveighed against by photographers, who often charge it with defects which might be overcome by increased attention on their part. Many photographers desire a very glossy surface to their paper, which is easily attainable by securing a concentrated surface of white of egg; but these also require, at the same time, that the paper shall tone quite as rapidly as one which has a thinner film of albumen on its surface. This, as a matter of course, cannot be the case; for the former kind of paper requires very particular and especial treatment, as we shall state presently. Moreover, one cannot very well demand, seeing that there is no other practical method of drying at hand than that of hanging up the prepared sheets, that albumenized paper with a single coating shall yield pictures from the top of the sheet of equal vigour to those printed on the lower portion, upon which there is so much more albumen.

The observation, often made, that albumenized paper, and especially that of a white description, soon becomes yellow, has its reason in the different kind of sizing material applied to the original paper. The consumer may help himself in this matter by acidifying the sensitizing bath, and only employing fresh soda solution in the fixing of such papers. We might quote many such points, but will confine ourselves to giving a few short notes which it is well to observe in dealing with albumenized paper; and we may state that due attention to these will result in the obtaining of favourable results.

a.—The silver bath, which may be prepared of a strength of one to eight, or one to ten, should be kept at a uniform strength; maintaining the same in motion, and floating for equal periods, are the points to be attended to.

b.—In the case of highly-albumenized paper it is essential, so as to prevent blistering, to prepare the soda bath fresh every day, and not too strong (say 1 to 10 or 1 to 12). A weak soda bath never requires to act for longer than a quarter of an hour, in order to fix pictures thoroughly.

c.—The first washing waters before and after toning should be as nearly as possible of the same temperature.

d.—The toning bath is best employed of a weak nature, and in large quantity.

e.—Sensitized paper, as likewise finished prints, should never be dried too rapidly. The latter are best mounted while in a damp state, in order to prevent any tearing or splitting of the film in the operation. It is also well not to allow prints to dry before being put through the rolling-press.

## DISRUPTION IN THE PHOTOGRAPHIC SOCIETY.

ACCUMULATED communications are before us urging that some steps should be taken to give effect to the views of country members in relation to the present crisis in the Photographic Society. One of the most distinguished of provincial photographers, whilst deprecating the course which has been taken by the requisitionists, regrets that the council did not appeal to the country members against the vote of a few, rather than place the power in their hands by resignation. Another, an exhibitor of some of the finest pictures at the late exhibition, remarks, "What a sad mess these narrow-minded requisitionists have made of the society's affairs! The unfortunate thing is that at present the country members are quite powerless to help the council. I hope, however, that some means may be adopted to checkmate these men, and that the late council may once more be reinstated in office." Other communications are to the same effect. We are informed that the existing fragment of a council, consisting of five members, have resolved to bring out a number of the Journal before the next meeting, in which a counter-statement in opposition to that of the secretary in the last Journal will be made. As this must either form an extra number, or involve a delay of upwards of a month in issuing the report of the next meeting, a heavy expense to the society, or a serious inconvenience to members, must ensue. As it is possible the "innings" of the present authorities may terminate very abruptly, the issue of an extraordinary number of the Journal may possibly be their only chance of telling their own story in their own way. The committee of revision have devoted much time to their work, and intend, we believe, to send out a code of revised rules for the consideration of each member in the Journal referred to, the aim being to give form to their wishes before consulting the members generally. As an interval of less than a week exists, at the time we write, before the next meeting, and such rules have not yet been sent out, there will be brief time for their consideration before members are asked to vote upon them. We understand that Mr. Hooper intends to bring a motion before the meeting to the effect that the president, vice-presidents, treasurer, council, and secretary, be requested to resume office for the remainder of the session, and that at the next annual meeting all officers be elected in accordance with new rules to be decided upon. Dr. Mann and some other of the requisitionists will, we understand, support this motion; but whether it will meet with their general acceptance it is impossible to say. Such a course would be wise, as slowing a conciliatory spirit. We have no

means of even forming a guess of how far it would be acted upon by the council; but we can readily see how their acceptance of the position, with a distinct understanding that they would resign their offices into the hands of the society at the end of the year, would tranquilize and satisfy a large section of the society, and possibly prevent a serious secession of members. Mr. Hooper has asked us to press all members—country and otherwise—to attend and support his motion. We give his request publicity, but, for obvious reasons, we can do no more.

## NEGATIVE RETOUCHING.

A METHOD of preparing the photographic film for retouching is published by M. Julius Bildt in the *Photographisches Archiv*, which that gentleman states he has employed now for some time past to good purpose. In retouching, one of the great objects to be attained is, of course, a good surface upon which the pencil can be manipulated with facility; and M. Bildt says that the blacklead may be applied to the coating he recommends as readily and as effectively as upon paper.

Two solutions are made up, the one consisting of—

Gum-arabic...	...	...	1 part
Water	...	...	7 parts,

and the other compounded of—

Bichromate of potash	...	...	3 parts
Water	...	...	7 parts.

As much of the latter is added to the gum solution as will render the same of the colour of Madeira; the solution is then ready for use, and should be preserved and applied to the plate in the dark.

The negative is fixed and washed in the ordinary way, and before being dried is treated with the bichromate and gum liquid, which is poured over just as if it were collodion. The film is then dried in a place sheltered from the light, and then exposed to daylight for about half-an-hour. In this way a kind of insoluble varnish is formed over the negative, which is of a matt and very firm nature, upon which any kind of retouching may take place with the pencil. The Faber pencils Nos. 3 and 4 will be found easy to use upon the surface, the finest pencil-lines being possible in the shadows and elsewhere. This film of bichromated gum does not in any way injure the cliché, and may be employed as unhesitatingly as any other kind of negative varnish.

## A RESIN AND WAX TANNIN PROCESS.

M. CLAVIER, a photographer at Algiers, recently made known to the French Photographic Society the formula for a dry collodion process which permits him to obtain architectural negatives with a globe lens in twenty or thirty seconds, and landscapes, with foliage, in forty to seventy seconds; while interiors, which required a quarter of an hour with the ordinary tannin process, are secured with an exposure of two minutes.

A glass plate, after being thoroughly cleaned, is covered with a preliminary film of dilute albumen—the white of one egg dissolved in one litre of water—and, when dry, the collodion is applied. This is prepared in the under-mentioned proportions:—

Alcohol	...	...	50 drachms
Ether	...	...	70 "
Pyroxiline	...	1 to 1.20	"
Iodide of cadmium	...	0.30	"
Iodide of ammonium	...	0.30	"
Bromide of cadmium	...	0.60	"
Wax and resin solution	...	2	"

The solution is obtained by dissolving, by means of a water bath in a glass flask, three grammes of yellow wax or white wax in thirty drachms of alcohol, and, after cooling, a further similar amount of alcohol is added,

and the liquid filtered through blotting-paper. Finally, 3.75 grammes of powdered colophane or gum resin are put into the liquid.

The plate, having been coated with this resinous collodion, is sensitised in an eight per cent. silver bath, slightly acid; and having been immersed for a sufficient period, it is taken out and carefully washed. It is then covered with a one per cent. solution of tannin in water.

Plates thus prepared will keep good for a very long time without losing their sensitiveness; they may be developed by any process applicable to dry plates.

GELATINING ALBUMENIZED PRINTS.

THE *Photographisches Archiv* contains a bit of practical advice on the question of coating albumenized pictures with gelatine to give them a *glacé* appearance. A very great deal, we are told, depends upon warming the glass plate which is pressed against the gelatine surface, for the latter, as the experimenter will know, is very liable to become disfigured by the presence of air-bubbles. The mode of operating given by M. Meusesen in the above-named journal is very simple, large pictures being treated without difficulty. The prints are trimmed and mounted on cardboard, which leaves a margin of a quarter of an inch—rather broader than usual, therefore, and allows for cutting down after the gelatine has been applied. The prints are retouched, and then well rolled in a press. A thick solution of warm gelatine is prepared, and the pictures dipped bodily into it, and transferred, face downwards, to a glass plate which has been collodionised some half hour beforehand. This glass plate is kept in a warm state, being placed upon a heated lithographic stone for the purpose. If the gelatine is slightly heated, the plate pretty warm, and the collodion thoroughly dry, it is very seldom that one will be troubled with air-bubbles.

Any superfluous gelatine is removed by means of a sponge and warm water, after a rubber squeegee has been passed over the surface. In this way most excellent results are achieved, and, as rule, twelve pictures out of a dozen secured, so trustworthy is the process. In six hours after the pictures have been gelatinized they detach themselves spontaneously from the glass. As a rule, it is best to apply the gelatine in the evening, and the prints are then ready in the morning. One thing is essential: so that the pictures may not dry too rapidly, it is well to turn the glass uppermost, and lay the backs of the prints upon a damp cloth. Care and cleanliness are the two things needful to secure success.

ALBUMEN EMULSIONS OF SILVER SALTS.

OUR correspondent, "A Deaf and Dumb Artist," sends us formulæ of an albumen emulsion of chloride of silver, and a similar emulsion of bromide of silver, with each of which, he states, he has obtained promising results. For the chloride of silver emulsion, he says, to the white of one egg, well beaten, add—

- Chloride of ammonium ... 4 grains
- Water (distilled) ... 30 minims.

Then take—

- Nitrate of silver ... 17 grains
- Water (distilled) ... 20 minims.

Add sufficient liquid ammonia to re-dissolve the brown precipitate of oxide of silver. Then drop this slowly into the albumen solution, shaking meanwhile. Paper or glass coated with this is very sensitive. It may be toned and fixed as usual.

The bromide emulsion in albumen is described as follows:—"The white of one egg is beaten as before, and seven grains of bromide of ammonium added, and sufficient ammonia-nitrate of silver added to convert the bromide into bromide of silver. A plate coated with this emulsion subsequently, when the film is set, covered, by immer-

sion or pouring, with a solution of nitrate of silver containing twenty grains of nitrate and three drops of nitric acid to the ounce. It is then washed and dried. Any preservative may be used, and either alkaline or acid development answers."

ON A NEW STUDIO.

BY SAMUEL FRY.

IN accordance with numerous desires expressed that I would send further particulars of my studio, I beg to give herewith a sectional sketch and two ground-plans: the former will explain the height and arrangement of the glass, and the latter the internal arrangements.

One primary intention in the building was simplicity in working, and I believe, after a year's experience with every variety of picture from miniature to eighteen inches, that I may say I never before saw a room in which, with so little trouble, and in so short a time, such a great variety of pictures can be taken.

There are no side blinds, and none are required. A much better effect is given, and one far more under control, by two lofty folding screens, as shown on the ground-plan. These are made of light but strong frame-work,

and three of the four folds are covered with dark green tannin, the other having book muslin strained over it. By the careful manipulation of these screens (and, in particular, the muslin-covered part between the sitter and the light) very fine effects can be produced, infinitely easier than by roller blinds. The muslin filtration communicates a soft and pearly tone to the negative, reducing retouching to a minimum, and producing (with proper arrangements of the upper light) those silvery lights on the nose and rounding of the features so much sought for. When the light is very powerful, these screens may be advanced more towards the centre, and in advance of the sitter. For hard-featured, stern-looking persons, with deep-set eyes, I find I have a power not obtained by other means.

Two spring roller-blinds cover the upper light, and, during fine weather, for eight months of the year, I find that the one nearest over the sitter should be drawn considerably down, and the other one about one-fourth down. But every sitter requires this to be carefully watched.

Very different treatment is desirable for a thin, sharp-featured person, and for a round, chubby one. It is well to have a large cord to the blinds, and then, standing near the camera, watch the effect on the face of alteration. The same with the screen. Very little is required in the way of lighting up the off side of the face; from the large extent of the upper window sufficient illumination is ordinarily found, which in dull weather is supplemented by a

screen covered with grey drawing-paper, being a colour that does not reflect in the eyes. Many of the finest published pictures of a well-known firm are injured, in the eyes of connoisseurs, by the inveterate habit of placing a strong white reflected on the dark side. Avoid this. A silver-grey paper on the room, or a distant screen, will give all that is desirable.

The craving after pictures without shadow is one the cultivated photographer should, by example and precept, discourage. Let him show as specimens, and take in practice, pictures with good transparent shadow, and he will soon find an appreciative public. It is astonishing how gladly the public grasp at the power in a photographer to communicate a feeling of art to his pictures. No mistake can be greater than to suppose he should be a mere delegate to represent only what can be seen. It should be his province to communicate refinement and delicacy to the productions of his skill, and this is perfectly compatible with the most exact adherence to the lineaments of his sitter.

One of the points to which I gave most attention in the building of this room, and which has turned out in every way successful, was to have complete means of working out a number of variations in shadow on Rembrandt pictures. Look at ground-plan No. 2. At the north end, in the dead wall, is a window of ground glass. When at work at fully lighted pictures, a large background, on a frame and castors, covers this up; but when I wish to do a Rembrandt of the now popular kind, with profile and outline in vivid light, and the rest in subdued tones, this frame (D) is drawn out at the left side, the sitter is about A, and the camera on the line marked by dots. By varying the place of the sitter, a large variety of effects of most beautiful lighting are produced. Here a grey reflector is wanted for the off-side. Those who have worked at figures near a window in a sitting room, the spectator being in the darkened end of the room, and watching the play of light on a face, and the lovely gradations, and the immense variety at command, will know what I mean. I had often felt this in a room in my own house, and determined to make in my new studio such a window. The effects obtained are just what was wanted, and the alteration of the lighting is done in half a minute. Just double the exposure is required, but if you think this objectionable, or the plan too troublesome, do not try it, for if you once begin to supply your sitters with pictures taken with this light, they will take care you are obliged to continue them.

Another kind of shadow picture, requiring no more than the usual exposure, is taken, as shown on ground-plan No. 1. The dotted screen is shown in the centre, and the sitter at K, the camera at B K. During exposure the lens must be carefully shielded, being opposite the light. The pictures produced here admit of fuller faced shadow pictures, with the details of the darker side more decided than in the other system, and without the strange outline illumination. It is suited for the *nez retroussé* and celestial, for round, plum-pudding faces, frequently giving them a grace and distinction of look that surprises none more than the possessor of the useful countenance aforesaid.

To be able to make plain people look well in a picture, and to light up an ordinary face with animation, should be the aim of photography in good hands. Nothing does more to advance a man in the estimation of those who want pictures done than to see pictures of people they know who are shown to advantage in photographs. How can you do this, unless you possess the means to do it by having the best possible lighting in your studio?

In plan No. 1, as shown at A A, the sitter can be taken at either end of the room; the camera simply requires turning round. A very important point is, that in this studio there is no glare of light; thus fair complexions and blue eyes are exceedingly well given. It is rare to see in photographs the Saxou complexion adequately represented.

Even in skilled hands, there is too much black and white about the hair and complexion. Of course lighting above will not do this; careful timing and developing, as also rinting, are wanted, and in each the eye ever watchful to detect and suppress what is unsuitable.

Next week I will touch on certain arrangements for ventilating, warming, &c., and a number of small but important details, which are found to add much to successful working.

#### PERMANENT SENSITIVE PAPER.

In the *Photographisches Archiv*, M. Fritz Haugk gives a method for producing sensitive paper which will remain good for a long time, and which, he states, appears very similar to the material which M. Romain Talbot manufactured and sold in Berlin some time ago. It was destined by M. Talbot more especially for non-photographers and those who desired occasionally to make reproductions from plans and maps and such like, and who would therefore wish to have a stock of sensitive paper at hand for employment now and then. Talbot's paper has been well received in many establishments, and photographers may therefore be desirous of knowing how a paper of the kind might be prepared by themselves.

Good stout albumen paper, or plain arrowroot paper, is floated on a bath made up of—

Water	...	...	...	32	parts
Nitrate of silver	...	...	...	3	„
Citric acid	...	...	...	1	part
Tartaric acid	...	...	...	$\frac{1}{2}$	„

One minute is amply sufficient for the paper to be in contact with this liquid, and after this interval the paper is dried, and finally drawn slowly through a weak solution of tartaric acid. In preparing this last named solution, spring water may be employed without fear.

The paper prepared in this manner keeps well, and prints rapidly and vigorously. It requires, however, for toning, a very strong and alkaline toning bath, although, when the paper is employed for technical or scientific purposes, any toning of the print is generally superfluous. The paper will preserve its whiteness for two or three months, provided it is carefully stored away from the light and from a damp atmosphere.

#### VISITS TO REMARKABLE STUDIOS.

##### M. REUTLINGER'S STUDIO, IN PARIS.

WE purpose adding to the list of noteworthy studios, which we have from time to time described after personal inspection, some details of the principal studios in Paris, as described by our esteemed French correspondent, Mons. Ernest Lacan, in our Philadelphia contemporary, in a series of articles on the subject he is contributing to that journal, commencing with the studio of M. Reutlinger, in the Boulevard Montmartre. M. Reutlinger is described as a German who has preserved, during many years' residence in Paris, his Teutonic type and accent. "He is of medium height, inclining to corpulence, with a round face. His hair, which falls rather low on the forehead, is brown, short, and slightly wavy. His moustache and goatee both thin, delicate, and grizzly. His eyes, slightly sunken, have a piercing look under the spectacles which he always wears. He is about fifty years of age, but does not appear so old. He has no special dress for his work, and nothing eccentric in his garments. There is an air of simplicity and good-nature about him which is not belied by his words."

After thus much of the man, we proceed to his studio, which is "in the fifth and sixth stories of a fine house situate on the Boulevard Montmartre, between Vivienne and Richelieu Streets. Two frames hung at the door, which opens on the Boulevard, are filled with attractive portraits (card and imperial size) of our female theatrical celebrities. It is about as much of an exhibition as is

usually made by Parisian photographers. A handsome and wide stairway leads to the studio." After a description of the reception and specimen rooms, M. Lacan proceeds to the studio, of the interior of which he gives the following sketch, taken from the entrance door:—

The gallery, which we are told, is "formed of two mansards, which have been united by removing the partition that separated them, is 12 metres (39 feet) in length by only 4 metres (13 feet) in breadth. Its height to the top of the upper sash is hardly 5 metres (16 feet 3 inches). The light comes from the north, but in sunny days it is far from being good, on account of the yellow reflections from the houses situate on the other side of the Boulevard, the fronts of which have a southern exposure. It is by means of an ingenious combination of white and blue shades that the artist succeeds in correcting this defective light, so as to obtain the charming effects so much admired in his productions. As may be seen in the drawing, these curtain screens, A, B, C, can be used separately simply by means of cords and pulleys. They move from the bottom to the top on the side sashes, and slide on the contrary from the top to the bottom on the upper sashes. When they are not in use they are gathered together as represented at D, E, F; besides these, other white curtains, G, can be moved in the ordinary manner from side to side. This, I repeat, is the only secret by which the eminent photographer can execute, in a gallery so unfavourable in many particulars, works which with justice are classed among the finest productions of photographic art. It may be said that he handles light as a painter does colour."

M. Lacan adds: "This establishment has remained, in all respects, the type of those galleries in which the first disciples of Niepce and Daguerre inaugurated their art, and made their reputations and their fortunes. Since 1852, Reutlinger has been obliged to enlarge his establishment in order to accommodate the great increase of his custom and his work. Experience has forced him to make numerous changes in his apparatus and his processes, but the appearance of the operating room in which he works, and of the reception-rooms to which the public are admitted, have suffered but very slight changes. When I enter his place it seems to me that all at once I become twenty years younger; it would be very desirable that all his sitters should experience physically the same effect."

We need not pursue the narrative into all the details of the store rooms, various working rooms, and reception rooms, where, in the last mentioned, we are told that "a

young lady, Reutlinger's beautiful daughter, who speaks several languages, receives the customers, and does the honours of these salons."

"The printing is done in the upper storey—that is to say, on the roof, which forms a terrace. There we find five hundred printing frames, which are constantly in use. Seven persons divide among them the careful work required in the operation of printing. The customers of Reutlinger are not composed of the ordinary public only who have their portraits taken, but it includes also the dealers in specialities and commission merchants, to whom he makes daily deliveries of the portraits of the celebrities of every description—actors and actresses, statesmen, artists, authors, queens of the *demi-moude*, &c., of which he is the publisher, and of which the trade requires a large number.

"Reutlinger employs twenty-eight persons, without counting the colourists and retouchers, who work in their rooms at home. These twenty-eight persons are thus divided: two at the desk, one for the salesroom, two in the waiting-room, three in the gallery, three in the laboratory, seven at retouching, three in the preparation of the paper, seven in the printing and mounting of the prints."

We may add, in conclusion, that M. Lacan's interesting details bring back vividly all the details we saw in a pleasant visit to this establishment which we briefly described some years ago.

#### HOW TO TREAT AND REALISE GOLD AND SILVER RESIDUES.

[M. L. G. KLEFFEL, of Berlin, who is known to our readers as a competent authority on photography, and who for some time conducted the periodical *Licht*, has favoured us with a seventh edition of his Handbook which is just published. We extract from it the article touching gold and silver residues, as the same is not only a very complete resumé of the subject, but cites the simplest and easiest methods, such as may be performed by photographers of ordinary ability.]

1. *Separation of chloride of silver from silver baths and washing waters which contain no hyposulphite of soda.*—It is a well-known fact that in the silver printing process only twenty-five parts out of every hundred of nitrate silver actually come into operation, and the remainder would inevitably be lost if one did not take the trouble to recover it from the residues. This circumstance, therefore, deserves the serious attention of every earnest photographer, more especially as the exercise of economy in the matter requires the expenditure of but very little trouble. All liquids which contain silver, whether old baths, solutions, or rinsings, with the exception of those which contain hyposulphite of soda, are put together in a glass or glazed vessel, and collected until such time as the quantity warrants the recovery of the same. To obtain the silver in the form of chloride, a mixture is prepared of one part pure muriatic acid and one part water, and this is added to the vessel of residue liquids until any tendency to become turbid has disappeared. To make quite sure, the liquid is stirred up with a glass rod, and allowed to stand until the surface has become clear, when further addition of acid will prove whether the disposition to become turbid is, or is not, present; more acid is, of course, added if turbidity ensues. After a few days the chloride of silver will have become deposited at the bottom of the vessel, and the clear portion of the liquid is then decanted off. Further quantities of the liquids are collected, and the chloride again thrown down, until at last there is a goodly mass at the bottom of the vessel.

The moist chloride of silver contains a good deal of acid, and this must be separated if the compound is required in a pure state. To do this, it is only necessary to wash it

in several changes of water until it fails any longer to redden blue litmus paper. When this result has been secured, the moist chloride of silver is put into an evaporating dish and heated, being well stirred the while, until no more moisture is given off. The chloride of silver is now in a state suitable for sale, exchange, or reduction.

The pulverizing of the chloride of silver is altogether unnecessary, and it is quite sufficient to break it into fragments of the size of beans or peas; neither need it be stored away from the light, for the circumstance of the compounds turning black has no effect upon the metallic silver. Chloride of silver is not soluble in water, but in ammonia, and a solution of hyposulphite of soda in water. During the drying of the compound, and in stirring, care should be taken not to breathe the vapour, as it produces a disagreeable feeling in the neck and nose. It is to the interest of the photographer that no impurity should enter into the chloride of silver, as otherwise the metallic silver afterwards produced has a lesser value, and consequently is not paid for so well. It is also a matter of importance not to allow any filter-paper to enter the residue vessel, for it is impossible to separate the same afterwards, and the buyer will make a serious reduction in the price he offers for the material. The purer and drier the chloride of silver, the higher the price it will fetch.

2. *Treatment of residues containing hyposulphite of soda.*—These liquids are collected in like manner. When a large quantity has been brought together, a solution of sulphide of potassium in water is prepared, added to the liquid, which is stirred, and, after standing some days, the upper portion of the liquid is poured off. The black mass at the bottom of the vessel is sulphide of silver; it is treated in the same way as the chloride, but is of less value. One hundred grammes of sulphide of potassium precipitate about double the quantity of sulphide of silver; but as the action of the sulphide of potassium cannot be watched, it is well not to add too little of it, so as to make certain that all the silver has been thrown down. It should, however, be remembered that, as a rule, there is but little silver in these liquids.

3. *Treatment of paper which comes into contact with silver.* When a quantity of cuttings, filters, and other bits of papers which contain silver have been collected, it is best not to sell the same in this form, but to reduce them to ashes, and then smelt the latter. The burning is best done by lighting a handful of the cuttings in an old iron pot, and keeping up the conflagration by adding the paper gradually until the whole stock has been consumed. An iron rod may be used for turning over the ashes, to see that they are perfectly burnt, and, when cold, they are rubbed down to make a denser mass. The paper from fixed prints contains a very small amount of silver; the ash from it is so light that it often flies away in the air, and is not worth the trouble of collecting.

4. *Reduction of chloride of silver and ashes.*—This operation can be undertaken in any good draught furnace or fire, but it is more convenient if you can get a smith to do it for you in his forge. When large quantities are treated, it will pay to have a small smelting furnace of one's own. The method I recommend is the one employed by most smelters in the trade; if the heat is sufficient, it gives up the silver in a pure state, and it is, moreover, very simple, and the cheapest that can be employed.

The smelting of chloride of silver and ash is undertaken in Hessian crucibles, which can be cheaply purchased of any dimensions. It is well to rub the interior with white chalk to prevent the silver, when molten, attaching itself in beads to the sides of the crucible. The best fluxing medium is powdered calcined soda. It is well mixed with the chloride of silver in equal proportions, the mixture filling three parts of the crucible; and before the latter is put into the furnace it must be thoroughly warmed, as otherwise it will fracture. Under the crucible is put, as a precautionary measure, a substratum of

Hessian clay, so that in case the crucible is broken the silver shall not be lost. A good fire is lit by means of wood; the crucible, with its clay stand, is put in and surrounded by coke; and the heating is hastened by the aid of a bellows. Care is taken from time to time to see that the heat is kept steady, coke being added as required. The glowing mass in the crucible begins at first to expand, rising to the edge of the crucible; if a boiling over of the mass is feared, a little common salt is thrown in, which has the effect of quieting the mass, and making it sink down again. The more intense the heat the more quickly will the mass fuse, and the temperature is maintained until no more bubbles appear, and the glowing white mass becomes quiet and liquid. A certain sign that the smelting is completed is when the surface is quite smooth, and moves to and fro. If stirred with an iron rod, the mass should drop off quickly when the rod is withdrawn; if it pulls out in strings, it is a sign that more heat is necessary.

When convinced that the process is at an end, the crucible is lifted from the furnace by means of a pair of tongs, put in a convenient place to cool, and finally broken to obtain the ingot. If it is desired to have the silver in some special shape, it is poured, while in a molten state, from the crucible into an iron mould, previously heated. If the mass has not been sufficiently heated in the furnace, a portion of it will be found remaining in the soda slag.

Eight parts by weight of good pure chloride of silver yield five parts of metallic silver; when operating with small quantities, and with extraordinary care, as much as three parts of metallic silver may be obtained from four parts of dry chloride; but in ordinary work, with large quantities, the first named proportions are very near the truth.

To smelt ashes only, it is necessary to add but one part of soda to three parts of ash; the two substances are intimately mixed, and the mixture pressed tightly into the crucible until the latter is quite full. No fear need be entertained of any boiling over in the operation, as there is not enough soda to do any harm. The smelting of paper ashes is a quicker operation than that of the chloride of silver.

If it is desired to smelt into one mass several small ingots or bars of silver, this is best done in a graphite crucible. A much lower temperature is needed for the purpose as is the case with chloride of silver. When the silver has been melted, it is well to throw into the crucible a spoonful of coarsely powdered charcoal, which has the effect of freeing the mass from any impurities that may be present.

5. *Smelting sulphide of silver.*—The proportion of soda to be added in this case is the same as with the chloride. It is necessary, however, to mix with the mass some iron filings, as otherwise the silver will never become separated. To one pound of sulphide of silver one ounce and a-half of filings is sufficient; the same should not, however, contain any brass or copper, but consist wholly of iron.

6. *Separation of gold from old baths and solutions.*—There are two ways of obtaining pure gold from old baths: either the liquids are evaporated to dryness, and the residue is melted in a crucible; or the gold is thrown down by adding sulphate of iron. The first method is not to be recommended, by reason of the time required for evaporating large quantities of liquid, and also because gold baths are, as a rule, so much exhausted that the result would be scarcely worth the trouble of working for, nor would the expense of the heating arrangements be covered. For this reason, I have confined myself to describing the second method, as being the more practicable.

When a large quantity of gold baths and solutions have been collected, the same being kept free from impurity, a solution is prepared of twelve parts of sulphate of iron in twenty-four parts of hot water; this is diluted with three times as much water, and filtered. The solution, after

filtering, must still be warm, or, if this is not the case, it is to be slightly heated. The waste gold liquid is also filtered, and is then poured, stirring the white with a glass rod, into the iron solution, when the latter at once assumes a turbid, dark-brown colour. When the gold solution has all been acted upon, the vessel is allowed to stand quietly for from twelve to twenty-four hours, and a brown precipitate will then be found, consisting of gold.

In order to test whether sufficient sulphate of iron has been employed to precipitate all the gold, some of the clear brown liquid at the top of the vessel is put into a test-tube and warmed over a spirit lamp, together with a few drops of the iron solution. If it remain clear, all the gold has been thrown down; but if it become turbid on the addition of the iron, then a further supply of this, in a warm state, must be added to the residue.

When the gold has been all precipitated, and the liquid become transparent, the latter is carefully poured off. To the residue is added a few drachms of pure hydrochloric acid, and the vessel containing it shaken; then water is added, and the contents allowed to remain for some hours, after which the water is poured off again. This washing is continued until the water pours off quite free from acid, or, in other words, until it fails to impart a pink tint to blue litmus paper. When this has been satisfactorily accomplished, all the water is poured off, and the residue is dried by putting it upon a sandbath or warm oven. The precipitate thus obtained is collected by means of a glass spatula, and may be considered as pure metallic gold. It presents a cinnamon-brown tint, and, if pressed lightly with the finger nail, assumes a metallic lustre.

### Correspondence.

#### THE PHOTOGRAPHIC SOCIETY.

SIR,—Will you allow me to state that the communication in the columns of your contemporary, dated from Brussels, was not written by me, and that I do not know any gentleman of the same name resident in this city. As my name is so well known all over the world, and the weight attached to my opinions on such a subject as the position and character of the Photographic Society of London so overwhelming, I feel it the more important to ask you to publish this denial—especially as I do not endorse the opinions of the writer of the letter in question, who appears to be a person “wise in his own conceit;” and your readers know Solomon says “there is more hope of a fool than of him.” My only aim is, however, to assure you that the minute interest in the proceedings of the society is not confined to Brussels. In the last letter I received from Moscow just the same keen concern in the convulsions of your little society was manifested, and I have reason to believe that the proceedings of the conspirators are as eagerly watched in Timbuctoo as they are in Brussels.—Your obedient servant,  
W. J. ONSLOW.  
*Rue de Namur, Brussels.*

### Talk in the Studio.

OBITUARY.—The name of one of the gallant gentlemen who fell at the battle of Amoaful, Captain Buckle, was well-known to photographers. He was the son of one of the earliest photographers, whose name descends to the present generation of workers by their knowledge of his useful little contrivance, “Buckle’s brush.”

PHOTOGRAPHIC SOCIETY OF LONDON.—Mr. G. Hooper asks us to announce that at the meeting of the Photographic Society to be held on Tuesday evening, he will move that the president, vice-presidents, treasurer, council, and secretary be requested to resume office for the present year. The aim of his motion is to secure a state of settled and trusted management during the changes in the laws of the society, after which a new council may be elected under the new regime. He earnestly wishes all members interested in the welfare of the society to attend and vote for his motion.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this society, which will be held at the Rooms of the Society of Arts, John Street, Adelphi, on Thursday, March 12th, Mr. S. Fry will read a paper “On Studios,” illustrated by a model.

PHOTOGRAPHY AND THE TELEGRAPH.—Instantaneous photography has been proposed for registering the deflections of a new and very delicate electric telegraph, which is described in the *Times*. The indicator is described as consisting of a strip of gold leaf, which is deflected either to the right or to the left according as a positive or negative current is sent through it, and that these vibrations of the leaf, being magnified, are read off by the operator. Mr. Highton states that the deflections of the leaf might be recorded by instantaneous photography. We presume that some of the rapid dry films which are now available might be used in conjunction with this instrument.

HANDY WEIGHTS AND MEASURES.—We learn from the *Journal of the Society of Arts* that the bronze Victoria penny is precisely one-third of an ounce in weight, and as this weight is the postal unit for continental letters, the penny will be found a convenient weight. It is also stated that a bronze halfpenny is exactly an inch broad, and therefore gives us a very convenient measure. Laid on an Ordnance map of the inch scale the halfpenny covers just 500 acres.

CAPTAIN ABNEY’S INSTRUCTION BOOK.—In an able review of the excellent manual recently issued by Captain Abney, the *Derbyshire Advertiser* says:—“Under the unassuming title of ‘Instruction in Photography,’ Captain Abney, of the Royal Engineers, the eldest son of our respected townsman the Rev. Prebendary E. H. Abney, vicar of St. Alkmund’s, Derby, and rural dean, has produced a work which, for perspicuity of style and excellence of arrangement in its special application, has not yet been surpassed, at all events in so small a compass. Nor is it by any means confined to the mere rudiments of the art. On the contrary, it treats most learnedly and cogently of the theory of it, and testifies to the profound acquaintance with the subject possessed by the author. At an age when so many young men are wondering what is to be done with a plentiful crop of wild oats which they have on hand, Captain Abney, by dint of hard work and assiduous study of his profession, finds himself in the important position of Instructor in Photography at the Military Engineering School at Chatham. And in order that our readers may form some idea what instruction to the Royal Engineers means, and what manner of man their instructor must be, we will give them a short abstract of the book. It means that he must know thoroughly the theory and application of modern photography as practised in the studio and the field; the various ‘dry processes,’ as they are called, of which some five or six are given, and by means of which you may, if you like, go out for a fortnight’s tour, expose your plates, and come home and develop them quietly at your leisure; the calotype process, in which paper takes the place of glass as the negative; the carbon process, which gives you a perfectly indestructible print which you may hang up amongst your *penates* in the pleasing assurance that it not will fade away before your eyes in twelve months’ time; the photo-lithographic, photo-zincographic, and heliotype processes, together with silver printing, and other special applications of photography too numerous to mention.”

### To Correspondents.

W. J. STILLMAN writes to say that Mr. Thomas withdrew from the committee for the revision of the laws of the Photographic Society under circumstances which he thinks were very amusing. He adds:—“He accepted a place on the committee, and when we met he offered his real co-operation only on the condition that we should do nothing! Having been deputed by the society for a definite duty, and having accepted the duty, we were required, as the condition of Mr. Thomas’s assistance, that we should agree to disperse without action, after the manner of the farmer’s boys, of whom one was doing nothing and the other helping him.” Mr. Stillman proceeds to stigmatize this course as “ridiculous” and “incomprehensible.” Without begrudging our correspondent the odd form of amusement he sees in such a matter, or discussing his estimate of Mr. Thomas’s conduct, we must point out that he is in error in regard to his facts. In the first place, Mr. Thomas did not, as his letter explains, wish the committee to “do nothing,” but that, before proceeding to the alteration of rules, they should communicate with all the members of the society to ascertain their views on the present crisis. Pursuing such a wise and honourable course Mr. Stillman regards as “doing nothing.” In the next place, we may remind Mr. Stillman that the committee to which he refers was really appointed by the requisitionists, and it was to secure the views and instructions of the whole society that Mr. Thomas desired a specific course to be taken. Mr. Stillman proceeds to admit that amongst those engaged in the agitation there is an

absence of harmony or unanimity. He says:—"I differ in several important points from the majority of the requisitionists, but as, in all such cases, union is necessary to victory, I waived my own minor opinions for the sake of union." This is candid; but how far such a victory will gratify the members of the society at large is scarcely a doubtful matter. Mr. Stillman says that "Commander Turton's letter seems to strain the point of fault-finding, for the sake of finding fault." "What," he asks, "have we or the new council to do with his not receiving a billotting paper, which should have been sent by the late secretary? Really he is like the wolf in the fable, and wants to gobble us up for the faults of our ancestors." Captain Turton neither says nor implies that his non-receipt of a voting paper was due to the new council, nor is his allusion to the voting paper the chief purport of his letter. That is a preliminary reference to a neglect or miscarriage in connection with the late executive. His chief aim, besides condemning the "factious and discreditable" conduct of the requisitionists, is to suggest united action to the whole of the members to depose the self-elected officers as a preliminary to any revision of the laws. Finally, Mr. Stillman recommends Captain Turton to wait. "If he is not satisfied with the assurances in behalf of country members, he had better wait and see what the committee of revision has to say, and then find fault, if he has any fault to find; at present, all that sort of thing is premature." Now this really is "amusing." Captain Turton and other country members are to wait until the requisitionists have settled everything past praying for, and then find fault!—when, of course, the reply will be, "Spoke too late; all is settled now." Why country members, whose rights and claims are in every respect equal to those of town members, should be told to wait, and they shall have attention by-and-bye, is certainly incomprehensible. The new rules not only ignore them, but actually prohibit them from taking part in the appointment of officers, and, on the hope these rules afford, country members are requested to wait in patience and faith!

**S. M.**—There is no work published on the subject you name, merely an allusion in an article or paper. The plan referred to consists in placing a plate of ground glass in the camera between the lens and sensitive plate, in order, in some slight degree, to modify and destroy the perfection of focus. It is not, we think, the best mode of securing the desired result. One of the best methods consists in the use of a plan similar to that we have described as employed in Jacobi's printing frame. Removing the stop during exposure, and giving half the time with the full aperture of the lens, is also easy and effective.

**G. AUTOL.**—You will find an article in our last volume, on page 403 (August 22), on the subject of producing large negatives, giving the various precautions necessary at much greater length than we can give them in this column. The collodion should be highly alcoholic, and may have water carefully added. A horny, repellent collodion should be carefully avoided. An iron developer, not too strong, should be used.

**A BEGINNER.**—You do not state whether you wish to commence with negatives or positives. We will assume the latter. Make your bath of the strength of forty grains of nitrate of silver to each ounce of water, and add two drops of nitric acid to ten ounces of the solution. Before adding this acid, however, add one grain of iodide of potassium to each ten ounces, and, if you can secure a few hours of sunshine, expose the bath to it, then filter, and add the acid. For developer, use fifteen grains of protosulphate of iron, two drops of nitric acid, and fifteen drops of acetic acid in an ounce of water. Fix with cyanide ten grains in an ounce of water, using the solution over and over. You will find the little work, "Photography in Four Lessons," published by Mr. Solomon, very useful.

**CARELESS.**—You should have stated the nature and extent of the crack. It may be difficult or impossible to prevent leakage; it may be easy. Shellac varnish, made by dissolving shellac in wood naphtha, run into the crack, may answer. Marine glue, skilfully applied to the crack, may answer well.

**B. J. \*S. H.**—The orange coloured solution of bichromate will answer well for a dark-room window. We see no reason for substituting any other acid for the dilute sulphuric acid.

**H. T. REED.**—We do not advocate long washing or long soaking, which does not necessarily mean perfect washing. Frequent changes of water, and thorough draining between each—or, better still after two or three rapid changes, placing all the prints in an even heap—and submitting them to severe pressure, and again washing a few times, will be found more efficient than long soaking. The loss of brilliancy to which you refer, after long soaking, simply illustrates the result of many hours' action of a very dilute hypo bath, for each washing water gradually acquires that character so long as there is a trace of hypo left in the print.

**A SUBSCRIBER.**—It is difficult, and scarcely safe, to transfer a varnished negative, as its adhesion to the glass is generally very firm. You may try applying a solution of gelatine, which in some cases will, on drying, lift away even a varnished film.

**G. H. BURTON.**—We added the address and posted the letter.

**J. H. W.**—The ordinary liq. amm. fort. of commerce we understand. 2. We have heard no further report or details of trials of the process to which you refer.

**EXHIBITOR.**—It is legitimate to send to an exhibition an enlargement made for you from one of your own negatives; but it will be honourable to give the name of the enlargers as well as your own.

**MACAULEY.**—You do not state from what kind of clothing you wish to remove the silver stains—whether from woollen or linen, white or coloured, fabrics. From linen or other washable fabric it is not difficult to remove the stains. From any kind of coloured clothing it is difficult to remove such stains without removing the colour as well. Apply solution of iodine, either made by dissolving iodine in alcohol, or by dissolving iodine in an aqueous solution of iodide of potassium. Then apply cyanide of potassium.

**AUSTRALIA.**—We regret that we cannot suggest any one likely to undertake the business duties you suggest; but we think you would be safe in giving commissions to most respectable dealers. We do not know anything of the method referred to in the paragraph you enclose, but think, had all its statements been authentic, more would have been heard of the matter. 2. Shellac, when dissolved in spirit, is often turbid at first, and requires some time for subsidence. Shellac is a compound body, and some portions of it, being insoluble, remain in suspension, gradually subsiding. The turbidity is not due to the castor oil, which is soluble in alcohol. 3. The application of iodine to a negative changes the colour to an olive green. It need not be changed right through, and care should be taken not to go too far, as it gradually may produce a light canary yellow, which is not non-actinic. 4. The bronze powder used in printing some cards has been ascertained to have an injurious action on prints, and is a frequent cause of yellow spots. 5. We are uncertain at what rate lantern slides can be sent by post. The dealer will doubtless do the best of whom you may order them. 6. We are not familiar with those of Messrs. Pumphrey Bros.

**J. A. (Ikeston).**—The C lens is more rapid than the other, and would, we think, suit your studio. 2. The No. 2 will give you better results than No. 1. 3. The A is not so suitable as B for cards. 4. We do not know the whole-plate you name, but fancy that the other you have will answer best.

**A. J. COOK.**—As a rule we are not at liberty to give the name and address of any correspondent who writes under his initials only. The gentleman your name is a medical man. If you wish to consult him professionally, send us a stamped and addressed envelope, and we will forward you his name and address.

**G. BRUCE.**—Thanks. Possibly some means may yet be devised of enabling the country members to use their weight in averting the mischief which the agitation you so properly denounce has brought about.

**F. C. EARL.**—Thanks. We shall certainly try another year if such an arrangement as that you propose can possibly be brought about. We can see the desirability, but fear it is too late this year to do any good in the matter. Regarding the society, it is difficult to say what will be the issue. The "appeal to the country" appears on all hands to be regarded as the legitimate resource. We understand that a motion will be made at the meeting on Tuesday to invite back the officers to take charge of the society during the year, whilst changes and revision in the laws are made, and a fuller means of securing the influence of country members is provided. Whether such an unanimous vote will be secured, and whether, if secured, the result desired would follow, remains to be seen.

**R. W. ALDRIDGE.**—Thanks.

**A NON-RESIDENT MEMBER** writes an indignant letter to ask by "what right Mr. Sawyer, or any body of requisitionists, decide that the claims of country members should be postponed until the important 'questions affecting metropolitan members only' be disposed of?" He adds: "This insolent avowal, more than any other argument, shows the self-seeking aims of these men. The privileges of country members have been slight enough; one of the chief having been in the mere fact of membership in a society containing so many distinguished photographers. If that society be given over to the control of restless men, the majority of whose names are quite unknown to country members, men who coolly avow that their first aim was to secure their own objects, and pass rules which snub country members, the sooner country members resign the support of the society, as well as its management, to metropolitan members, the better." The comments on the members of council acting with the requisitionists are more severe than just, and our correspondent, on reflection, will be better pleased that we do not publish them.

**W. H. WATSON.**—Received; thanks.

**L. G. KLEFFEL.**—Many thanks. We have pleasure in publishing your remarks.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### THE TRANSIT OF VENUS—TRANSPARENT PAPER.

*The Transit of Venus.*—The photographic arrangements connected with the transit of Venus operations to be conducted by Government are now almost complete. Although the phenomenon, to which every astronomer is now looking forward, will not be visible until the month of December next, still, as all the stations at which observers will be placed are at a great distance from this country, the necessity for immediate action in the matter is obvious. It seems pretty well settled that a dry process will be employed on the occasion, and that the best dry process of Captain Abney, R.E., will be the one chosen. This officer has, indeed, been entrusted with the entire direction of the photographic work on the occasion in question, and we may heartily congratulate ourselves that the choice has fallen upon so efficient and eminent a photographer. No better selection could possibly have been made, for Captain Abney is not only a scientific and practical master of the art, but he is one well-skilled in the teaching of others. A school of instruction has been improvised at Greenwich, and here manipulations necessary in carrying on the operations, drilling in the movements, &c., are practised.

Fifteen Sappers are being instructed to become efficient photographers, to act as assistants to the five chiefs selected for the five different stations. Captain Abney, as the senior officer, has had the choice of stations, and has selected Alexandria, whither he will be accompanied by three of the Engineers. Lieut. Darwin, R.E., who is now in charge of the school at Greenwich, and who has been permanently attached to the Royal Naval College at Greenwich, will proceed to New Zealand in charge of the photographic work to be undertaken there, and will also be accompanied by three assistants. The third station will be on the Sandwich Islands, where the photographic arrangements will be under the direction of Lieut. Ramsden, R.N. The fourth station is in Kerguelen's Land, a rather out-of-the-way place, apparently, for it is described, rather indefinitely, as about two hundred miles south and east of the Cape of Good Hope. Father Perry will have command of this station, with Mr. Smith in charge of photography. The fifth station is Rodrigues, near the Mauritius, but no photographer has yet been appointed to this post of observation. The Indian Government will most likely send a party to a point at the extreme north of India, but with this station we at home have nothing to do. It is obvious that with stations so far away as these there is no time to be lost in making preparations; for in some cases a period of not less than six months must be allowed for the journey to the islands in the Southern Ocean. In the case of the Sandwich Islands and Kerguelen's Land, it will be necessary, in all probability, to take out, besides the scientific instruments, every necessary of life that may be required, for the actual locality of the station on the islands has not been determined on, and there will be, probably, nothing more hospitable than bare rocks and shingly beach to be found. As regards the preparations being made by Germany, we know that Dr. Krone, the president of the Dresden Photographic Society, has been ordered to proceed to the Auckland Islands, South of New Zealand, in June next, to obtain photographic records in that locality; while Professor Vogel, the president of the Berlin Society, will proceed to Japan. Both these gentlemen are well known to us through the medium of the photographic journals, and there are certainly no better men in the Fatherland who could have been selected for the delicate and arduous duty. So far as France is concerned, all we know at present is that M. Fizeau, a name known and honoured by all photographers, has been deputed by the French Government to undertake the instruction of those who will be entrusted with the photographic operations, and a school

for the purpose is now being constructed in the Luxemburg Gardens. It is considered that operations to be undertaken at such a distance require men more youthful than the French veteran photographer we have just named; but it is satisfactory to know that he will give his pupils the benefit of his experience, if he does not personally take part in the expedition itself. M. Janssen will doubtless have supreme charge of all scientific parties sent out from France. The station in Northern India, although nothing as yet is definitely fixed, will, no doubt, be under the charge—so far, at any rate, as the photographing is concerned—of Captain James Waterhouse, the Assistant Surveyor-General of India, who, as our readers know, is well fitted for the post, and who on a recent occasion proved himself to be a most accomplished astronomical photographer. One other ardent disciple of the camera remains to be mentioned, who has already undertaken most successful photo-astronomical work, and who intends once more to make independent observations of his own on the approaching important occasion: we mean Lord Lindsay. This distinguished amateur has elaborated a very complete arrangement for taking pictures in rapid succession of the phenomenon, and has spared neither time nor expense in securing efficient instruments. We may rest assured, therefore, that with such able and skilful masters of photography as we have mentioned, some highly valuable and trustworthy records will be secured of the transit of Venus across the sun's disc on the memorable 6th December, 1874.

*Transparent Paper.*—A good method of producing transfer or transparent paper is well worth knowing, because impregnating paper with wax or paraffin is at times not only inconvenient, but difficult to manage, if a large surface is to be uniformly treated. By mixing together three or four parts of absolute alcohol with one part of castor oil, a homogeneous mass is produced, which, when applied to the surface of paper by means of a brush, renders the same perfectly transparent. The operation is performed in a very few minutes, and the translucent character of the material is such that it can be printed through by photographic means very readily. Engravings, diagrams, drawings, sketches, and, indeed, any design executed on paper, may be thus transformed into a transparency, and if good paper has been employed of uniform texture and thickness, the result of printing by photography will be perfect. Of course, if the drawing is upon white paper, the copy will be in white lines upon a black ground, and this, although it would be quite sufficient for engineers and draughtsmen in order to keep fac-similes of their work, would not be always satisfactory. By treating the first copy again as a cliché, however, copies may be produced in their right sense, and in any number, the only apparatus required for the purpose being a printing-frame and a couple of baths. But the great advantage of this mode of producing transparencies lies in the fact that the castor oil may be removed from the paper at any moment by simply washing the transparency in alcohol; the oil is at once dissolved out, and the engraving or drawing so treated is restored to its pristine condition. No trace of oil or grease remains in or upon the paper.

#### FRENCH CORRESPONDENCE.

PHOTOGRAPHERS in Paris are still experimenting with the acceleration brought about by a preliminary exposure of sensitive plates or sensitive paper to light. At the meeting of the French Photographic Society held on the 6th March last, M. Ferrier gave an account of a very interesting experiment which he had made on the subject. He tried a process recently published, which consists in dividing the time of exposure into two periods, and commencing the exposure by furnishing the lens with a diaphragm, which is subsequently withdrawn. The author of this communication stated that such a proceeding reduced the actual pose of the object by one-half. M

Ferrier chose a landscape view for the purpose of trying the plan, and after having focussed and placed the prepared plate in the camera he uncovered the lens, which was furnished with a diaphragm having an opening of five millimetres. After twenty-five seconds had elapsed he withdrew the diaphragm, and continued the exposure with an opening of two centimetres for a second period of twenty-five seconds. The cliché resulting came up well on development. Immediately afterwards he produced another plate in the ordinary way with a large opening (two centimetres), and gave an exposure of one hundred seconds. This exposure, which was double as long, gave a result identical with the former one. The experiment repeated several times proved abundantly that by these means it was possible to diminish the exposure by one-half. Only in practice, no doubt, it would be preferable to employ, instead, one of the plans indicated by MM. Melchion, Franck de Villecholle, or Liebert, because the changing of the diaphragm during the operation of photographing may lead one to displace the apparatus; or, when it is a question of securing a portrait, the model may be disturbed by the movements made during the critical period of exposure. In one case or the other, one runs the risk of spoiling the result.

M. Fleury Hermagis exhibited to the society, at the last meeting, some new aplanatic lenses (of flint with a basis of minium chemically pure), which possess the most advantageous properties, to judge from the specimens which accompany M. Hermagis' note. They were views of monuments taken in Spain, and reproduced on a very large scale, the architectural lines without any distortion, and groups composed of a large number of people, executed by M. Boissonnas, of Geneva; seascapes, race horses, and troops on the march obtained instantaneously by M. Carlos Relvas, the skilful Portuguese artist. These were all much admired, especially a group of two magnificent cats, a greyhound, and several pigeons, who seemed to have given up their natural mobility of character in order to conform to the exigencies of photography. I consider it my duty to advise my English readers regarding these lenses, which have, besides, one more advantage, that of being of a moderate price.

M. Hermagis also presented the society with a varied collection of photo-lithographs and divers specimens of his process of engraving upon wood and metal, of a powder process upon enamel and porcelain, oil painting, &c.

M. Geymet submitted a volume indicative of the progress made with his mechanical printing process; it was a facsimile of a manuscript illustrated with sketches in pen-and-ink, the reproduction of which by any other means would have been very costly. By his photo-lithographic process he has been enabled to produce copies of the work at the price of fifty centimes a copy. This is a most important fact, considered from a publisher's point of view, as illustrated works may in this way be easily multiplied.

M. Geymet also exhibited a numerous collection of pictures, of cabinet size, printed by the aid of fatty ink, the fineness, modelling, tone, and general aspect of which were in every respect those of fine silver prints.

I will not do more than make mention of an apparatus designed by M. Champion for measuring the duration of exposure of instantaneous pictures, so to speak. The idea involved is an ingenious one. There is a kind of electric telegraph attached to the cap of the lens, which marks, with lines more or less long, the time during which the lens remains uncovered. It may be asked whether such an apparatus is of any practical value; for in taking instantaneous pictures it is a question rather of exposing as rapidly as possible than to know the actual duration of the pose. If, however, it may be of little service to photographers at large, this invention may nevertheless be made use of in particular instances, where a given time of exposure is necessary in the solution of a scientific problem.

Professor Stebbing, whose name is well known in France by all those who work the dry collodion process, having made quite a reputation through the excellence of the plates which he prepares, has communicated to me a method of a most simple and radical nature to get rid of the stains which are found too often upon negatives after printing for some time with silver paper. To make them disappear, it is sufficient, he assures me, to plunge the negative in a bath containing fifty per cent. of ammonia, and to rub the film lightly with a tuft of cotton wool, in those places which have been attacked, until the yellow stains disappear. This remedy is an infallible one, adds my correspondent.

It is now eighteen months since M. Fargier forwarded to the French Photographic Society a collection of prints obtained by carbon printing by means of a very simple process. I need merely say that he prepared a saline solution, which was placed in a porcelain dish, and upon this he floated a sheet of ordinary paper. This paper was then removed, dried, and placed in the frame under a negative. The image came up by degrees, and its progress could be well watched. When the exposure seemed to him sufficient, he floated the picture upon a bath of gelatine coloured with pigment, such as is employed in the preparation of carbon tissue. The gelatine fixed itself only to the portions of the sheet which had been impressed by light. He then washed in warm water, and the operation was finished.

To-day M. Fargier has completed this first communication by giving us the formula of the saline solution, which he had hitherto kept a secret. The liquid is thus constituted:—

Perchloride of iron ... ..	5 grammes
Citric acid ... ..	5 "
Water ... ..	100 "

The coloured gelatine mixture contains one drop of bichromate for every cubic centimetre of mixture.

Here again is the reverse of the process:—

Upon a bath of bichromate M. Fargier floats a sheet of ordinary albumenized paper, the albumen surface uppermost. After eight or ten minutes the albumen assumes a yellowish colour, and the sheet is dried in the dark. It is exposed under a negative or under a positive transparency, and the image produced is then floated upon a bath of gum coloured with some pigment to which a trace of protosulphate of iron has been added, and immediately afterwards the impression is washed in water.

The result is an imprint of the cliché or the transparent positive in all its details.

ERNEST LACAN.

#### AMERICAN CORRESPONDENCE.

VENTILATING THE DARK ROOM—HOW TO MAKE A "WONDER CAMERA"—THE PHOTOGRAPHER AND THE COLOURIST—HOW TO GROW AND IMPROVE.

*Ventilating the Dark Room.*—There are some things which must be continually pounded into people, lest they forget them, and very often this is the case in matters most essential to the health. One of these, and not the least important, is the subject of ventilation. Every time I go into a dark room and see the pale face of the manipulator I feel that I should do something more to induce photographers to take care of their health; and although it does seem as if it is with photographers like I was told in Dublin is the case with the Irish donkeys—"they never die" of the work they have to do—yet, without wishing to perpetuate a libernicism, I believe they would live longer if their work rooms were better ventilated. And while calling attention to the subject, I will give you a method of accomplishing the object named, which has been given me by Mr. R. J. Chute, as follows:—

"This question of ventilation is one that has puzzled so many much wiser heads than mine, that I am not over-sanguine in any recommendations I may make. A small room, however, such as

most of us use for the chemical operations connected with the making of negatives in the gallery, presents no such difficulties as the ventilation of the English Houses of Parliament, or the Halls of Congress at Washington, yet it is of no less importance to the occupant, and the best possible means that can be devised should be adopted to give every dark-room a thorough ventilation. It requires no elaborate system. The operations of natural laws in reference to the movements of currents of air are very simple, and it is only necessary that these should be observed to secure the desired result. It is well known that cold air is heavier than warm; also, most of the foul vapours and impure gases fall and mingle with the cold air, while the warm rarefied air rises. It is well known, also, that heat is one of the best of disinfectants.

"Now we have only to conform to these operations of natural laws to secure the end we desire.

Fig. 1.

on the wall, and a supposed flue, *f*, against which it is placed. The sheathing of the ventilator on the ceiling should be of *thin* material (a thin board sheathing, painted black, would be a good conductor of heat), so that the advantage of its broad surface may be gained by its being readily warmed by the heat of the room, and which will tend to give an upward current at all times. The diagram, Fig. 1, supposes the dark-room to be near the roof, as represented

Fig. 2.

at *C*. Should there be a flue or funnel at one side, as at *f*, then the ventilator, instead of passing out at the centre, might pass out as at *E*. But should the room be so situated that there could be no outlet through the ceiling, then place the ventilator as represented by the dotted lines at *g*. The fresh air supply is from the perforated pipe *D*, which should run on two or three sides of the room, and have a damper, to open or close, near the outer end. If connected with the outer air, which would probably be best, a fine wire gauze should be placed over the mouth. The perforations should be made so as to throw the air out horizontally into the room. The advantage of placing the supply-pipe at the top of the room will, I think, be readily seen. The cool air, as it enters the room from two or three sides, will immediately fall and cause a change in the air throughout the room; whereas, if the air were admitted at the bottom, or an open door or window depended upon for a supply, it would pass immediately into the ventilators, and the air in the upper part of the room scarcely be disturbed at all. Moreover, this arrangement will, I think, secure immunity from dust in a great measure. Though dust is sometimes raised, yet, if left to itself, it naturally falls, and with this arrangement it will be assisted in falling. Contrary to the system of ventilating at the top, which always tends to keep the dust whirling, this method carries it down, and keeps it there, or takes it off through the ventilator. The advantage of a perforated supply-pipe is that the air is not allowed to rush in with force in a great volume, which is sure to carry dust with it if there be any to be found, but

it must enter slowly, and be distributed over considerable surface; this neutralizes the force, and diffuses it throughout the room just as it is needed. Fig. 3 is a section of ventilator showing an interior automatic valve, which is intended to prevent a downward current. On one side of the pipe a piece is put in on an angle, filling about one-third of the opening, and on the upper edge of this the valve is hung. It is so constructed with a double thickness on the narrow side that its own weight will keep it open, but the least current of air coming down will close it. Care should be taken in hanging this valve to have it work perfectly free, for on this will its utility depend. The top of

the ventilator may be protected by a hood, as shown in the diagram, or any of the improved ventilators in common use might work well. In reasoning on this plan, it might be suggested that the currents of air will not move as desired—that is, the supply-pipe will be as likely to prove a means of egress as ingress; that the air, becoming warm at the top of the room, will escape through this pipe, and keep up an *outward* current instead of an inward one. This may prove true when a door or window is open, so that a pressure of air comes in from below, and then it will certainly do no harm if heated air escapes in that way; but when the room is closed, and the heavy air is drawn off from the lower part of the room by the ventilators, the pressure on the heated air above is removed, and the sort of vacuum there formed by the air, becoming continually rarefied by heat, will cause a constant rushing in of fresh air to supply it. This fresh supply falls, and takes the place of that being carried off—and so a continual circulation is kept up, giving a fresh and healthful atmosphere."

*How to Make a "Wonder Camera."*—A "wonder camera," as you undoubtedly know, is a sort of magic lantern so contrived as to enable one to use opaque objects for projection upon the screen instead of glass transparencies. For example, if a photographer wishes to show his customer how an enlargement from a carte will look, he simply has to put the carte in the "wonder camera" and "throw it up." Many enlargement sales may be made in this way. Any photographer may make a "wonder camera" for himself, and what follows will tell him how—a plan given me by Mr. T. Carter. He says:—

"After experiment I have succeeded in making the above instrument in a very simple manner. It consists of a wooden box with a top made of tin or sheet-iron; the chimney is made of the same material. The lens is the same as used upon a camera for making photographs. At the back of the box (as will be seen by reference to the plan and elevation) are two doors placed upon

Fig. 1.

hinges. When the box is in use the door *e* is kept closed. The other door consists of two parts placed at right angles to one another; the object of this is to fill the opening in the door *e* while the pictures are being attached to *c*; when *c* is swung into position opposite the lens placed at *b*, *d* is carried to one side. If stereoscopic views are to be shown, a slit may be cut at *e*, through which they may be inserted without opening the box. The

Fig. 2.

Fig. 3.

door *e* should be cut off a little at the bottom so as to admit air. The light is placed at *h*, as nearly opposite the picture as possible. It should be a strong light; an argand burner is the best. At the back of the light is a piece of tin bent into the form of a reflector. The light coming from *h* strikes *c*, and is reflected through the lens upon the screen. The plan of the box is represented with the top removed. I have given no dimensions, as they will depend upon the focal distance of the lens and height of the light. Care must be used to have the distance from the lens to *c*, when closed, equal to the focal distance."

(To be continued.)

## THE NEGATIVE BATH.

BY R. J. CHUTE.\*

Water	...	...	...	15 ounces
Nitrate of silver	...	...	...	1 ounce
Iodide of potassium	...	...	...	2 grains

THIS or a similar formula may be found in every work on photography, and is often reiterated in the journals; but as the nitrate bath is unlike most other chemical preparations we use, in that it is used indefinitely, it is a matter of the first importance that it should be kept in working condition after it is made. In order to do this it is necessary to know when it is in good order and when it is not; if it does not work well, to know what the difficulty is and how to apply the remedy.

If a bath fails to produce good work after it has been doing well, there is, of course, a cause for it. There may be said to be regular and irregular causes. The regular causes are those that come from the usual routine of work, and are exhaustion, becoming charged with ether and alcohol, dust and collodion films from the plates, and organic matter that dissolves and becomes a part of the solution. The first of these—exhaustion—produces pin-holes, by the strength becoming reduced, leaving iodide of silver in excess, which is deposited in fine crystals on the surface of the plate. The remedy for this is to filter and strengthen. The second—ether and alcohol in the bath—causes lines and markings in the direction that the plate stands in the camera, from the drying of the plate by the evaporation of the alcohol held in the solution. The remedy for this is to boil the bath partly away till the ether and alcohol are expelled. The third—dust and collodion films—may be avoided, in a great measure, by being careful to keep the plates well protected after being cleaned, dusted before coating, and then wiping carefully from the edges of the plate the heavy ridges of collodion that collect as it drains, and which, if left, often become loosened and break off in the bath. These may be avoided by a pin in the dipper, so that the plate shall not go to the bottom; or it may be kept well in motion during the coating. The sure remedy, however, is to filter.

The fourth cause, organic matter in solution, comes mostly from the plates, though any particles of soluble matter that fall into the bath are taken up. A fruitful cause, probably, is albumen from the glass. To avoid this care should be taken, in albumenizing, to prevent the albumen getting on the back of the plate; and also, in coating, to cover the surface as completely as possible, so that no albumen is exposed. The result of this condition of the bath is fog, streaks, and opaque spots. These may be removed by adding nitric acid, but the remedy is not very permanent, and it may be necessary to repeat the dose in a day or two; besides, the deposit in the negative, when developed, seems to be made up so largely of soluble matter, that, after fixing, the shadows and dark drapery will be almost destitute of detail or relief. The most effectual remedy for this trouble is to neutralize the bath and boil it. It may be neutralized with ammonia, bicarbonate of soda, cyanide of potassium, or permanganate of potash. The first two of these are preferable, if the bath is any way decidedly acid. The two last have rather a cleansing influence, and may often be used with success. The bath should not only be made neutral, but slightly alkaline. In this condition, when heat is applied, the foul matter is liberated, and falls to the bottom in a black mass. In renovating a bath in this way it should be filtered, after boiling, while it is yet warm. If allowed to cool, much of the matter thrown down may be re-dissolved, and the benefit of the operation in a measure lost. After filtering, it may be diluted with pure water to the proper strength, and pure nitric acid added till it shows a rather decided re-action on blue litmus-paper. The effect of the acid on the working condition of the bath cannot be de-

finitely ascertained until two or three hours after the addition of the acid.

With care to exclude as far as possible all extraneous matters, and avoid unnecessary doctoring, the treatment I have described will keep a bath in good condition indefinitely.

The practice of precipitating the iodide from a bath whenever it shows any signs of failure, no matter what the cause, is one that cannot be too strongly condemned. The only iodide I ever disturb is what little is precipitated, by adding to it a few ounces of pure water that has rinsed the bath-dish after drawing it off. This I do not filter out, but let it remain and be taken up again, if it will, when the bath is strengthened by boiling. In making up a bath after boiling it should be given its full bulk, filter, and add a few grains of silver, if any signs of milkiness appear, and it will come out bright and clear as crystal.

The irregular causes of failure are those that do not arise as the result of ordinary work, or that come from applying the wrong remedy in case of some trivial derangement. A common remedy with inexperienced operators for all sorts of difficulties is acid. Now acid is only beneficial in cases of an alkaline reaction, or such as I have already mentioned. Another irregular cause is getting the bath too strong; it will produce spots, streaks, and hard, coarse negatives. Dilute and filter, and the trouble will disappear. Another cause is quite sure to make its appearance on the approach of cold weather, unless great care is taken to keep up the temperature. The negative bath is the most easily disturbed by cold of all the chemicals used, or the effect of cold upon it produces the most annoying difficulties. And lastly, the bath should not be treated when the collodion, developer, or dirty plate holders are at fault. Be sure of the seat of difficulty, if possible, before applying a remedy.

## DEVELOPMENT.

BY D. H. CROSS.\*

THE proper development of the photographic impression involves a certain degree of dexterity in manipulation, as well as intelligence concerning the nature of the agents employed. Attention to composition, lighting, and exposure is of course very important, but this will avail little if the process of development does not receive its full share of attention. When the lighting and exposure are known to be faulty, there is at least a partial remedy in development. A knowledge of the nature of the agents used is important at the outset.

Protosalts of iron being used almost exclusively for development proper, I shall allude to them only.

The effect of protosulphate of iron when used alone is to give an image full of detail, but flat, grey, and devoid of contrast. The effect of acids of all kinds is to retard the action of the iron, and give contrasts or vigour. Acetic acid is used almost exclusively of late, both as a retarder and to give flowing properties to the solution. Formulae are of little use except as starting points, and as such I give one as good for a normal developer as any with which I am familiar.

Prepare a saturated solution of iron in water, and keep a sufficient quantity in readiness, as it will keep indefinitely. Prepare a second solution, 25 grains to the ounce of water (a common hydrometer is convenient, and sufficiently accurate for this purpose); add 3 or 4 ounces of acetic acid to 20 ounces of this solution; ordinarily, alcohol is not required. When it is to give flowing properties, the nitrate solution, "silver bath," should be partially evaporated. The person who develops should keep constantly in mind the strength of the light, the length of exposure, and the character of the lighting. If the lighting is soft and diffused, exposure may be shorter and developer stronger of acid, and the plate rocked more than if the lighting is decided and bold. If the lighting is decided and bold, the

\* Philadelphia Photographer.

\* Read before the Photographic Institute of Chicago.

exposure should be longer and the developer stronger of iron, and the plate should be held quite still. The quantity of developer used affects the result; the lesser quantity gives greater contrast. A weak developer should be used copiously, and the plate held still when great delicacy and softness are desired. Close observation and quick decision are required just at the moment development has commenced. We should be in readiness, with weak and strong developers, to vary the quantities of solution on the plate, and to vary the proportions of acid and iron, and to rock the plate or hold it still, as the effect requires. Generally some or all of the above means will enable us to produce the effect desired; sometimes, however, in large work, there will still be too much contrast; if so, add a few drops of alcohol to the ounce of developer before flowing the plate, and I think this fault will be effectually cured. Never having seen this remedy for excessive intensity used or mentioned, I would call attention to it as one of the most effectual and convenient at our disposal. Indeed, it is so potent an antidote for hardness or chalkiness that care must be exercised, or flatness will result. The larger the proportion of alcohol within certain limits, the softer the result.

A general fault is under-exposure; there is no remedy for very short exposures, and there is little danger of over-exposure. A negative that is thin and flat may be made more contrasting and intense easily with pyro and silver. We will now strive to increase contrasts. This may be done by short setting the collodion film, and short immersion in the bath; add acid to the developer, use little developer, and rock the plate. Use more silver in the pyro when redeveloping, or increase the proportion of acid in the pyro.

PHOTOGRAPHY IN NATURAL COLOURS.

BY M. DE SAINT FLOURENT.

In my first note addressed to the French Photographic Society in September last,\* I confined myself to describing the processes employed for the purpose of obtaining heliochromic pictures. Since then, some new observations have come under my notice, which I now propose to allude to, adding, at the same time, some details of the processes already described.

In the first place let me remark that heliochromic prints may be obtained without the intervention of a substance capable of giving, under the influence of solar rays, chlorine, or oxygen, in a nascent condition.

*Negative Heliochromic Impressions.*—If we expose, under a painting upon glass, a sheet of paper covered with sub-chloride of silver, prepared according to a plan which I will hereafter describe, and freed by washing from any excess of hydrochloric acid, we obtain, within a short time, a negative picture presenting all the colours of the model. This image will become a positive if the time of exposure is prolonged for a considerable period.

*Transformation of the Negative into a Positive.*—The result is exactly the same if, instead of employing the sub-chloride, we make use of the white chloride of silver, a circumstance which may be explained by the fact that the diffused light which traverses the glass at the same time as the coloured rays suffices to produce upon the surface of the paper a certain quantity of sub-chloride. The transformation of the negative image into a positive is due, perhaps, to the circumstance that in the last period of the reduction there is formed upon the surface of the paper in the parts corresponding to the whites of the image, products, the colours of which are relatively less deep than that of the sub-chloride. This action might also be due to the oxidising action of the less refrangible rays; but we shall recur to this subject again in the course of our remarks. A negative, it will be seen, may therefore be converted into a positive by continuing the exposure. The impression, on coming out of the frame, is plunged into a mixture

of nitrate of mercury and chloride of sodium, the latter being greatly in excess. In exposing, afterwards, to sunlight, the picture is seen to become positive, presenting feeble shadows, which are sometimes complementary to the primitive colours. It is probable that the saline mixture exercises, in this case, a more energetic chlorising action upon those parts of the image where the reduction has been more complete under the influence of light whilst the negative was produced.

*Preparation of the Sub-Chloride of Silver Paper.*—The sub-chloride of silver paper is prepared by plunging ordinary paper of good quality—whether albumenized or gelatinized, it does not signify—in an alcoholic solution of nitrate of silver of the undermentioned composition:—

Distilled water	...	...	20	parts
Nitrate of silver	...	...	20	„
Alcohol	...	...	100	„
Nitric acid	...	...	10	„

The nitrate of silver is dissolved in the distilled water, and the alcohol and acid added subsequently. The addition of a certain quantity of nitric acid is for the purpose of preventing the reduction of the silver salt by the alcohol, a reduction which otherwise would be very rapidly brought about.

The proportions here quoted need not be accurately followed; they may vary between very wide limits without any serious inconvenience resulting therefrom. Nevertheless, it is well to keep near to those proportions, if prints possessed of much intensity are required. On leaving the bath, the paper is pressed between sheets of blotting-paper, and then immersed in—

Hydrochloric acid	...	...	50	parts
Alcohol	...	...	50	„
Nitrate of uranium	...	...	1	part
Chloride of zinc	...	...	2	parts.

The chloride of zinc seems to impart vivacity to the colours, but it has the inconvenient quality, like the rest of the other chlorides, to tint the background when employed in too large a proportion. The nitrate of uranium added to the bath appears to have an influence upon the rapidity with which the sub-chloride of silver is formed.

The sheet of paper, on coming out of the hydrochloric acid bath, in which it should remain but a few minutes only, is exposed to light until it has taken a violet-blue tint if it is ordinary paper, or a violet-lavender if gelatinized or albumenized paper has been employed. If the colour is sufficiently intense there is no need for performing the operation a second time, and the paper may be forthwith employed.

Papers which have been albumenized, or even salted only, give excellent results; that known as Sutton paper, which may be obtained of M. Carotte, in Paris, is especially suitable. With papers of this kind I prefer to employ aqueous solutions. Sheets prepared with the sub-chloride may be preserved for a very long time if kept from the light, but, nevertheless, it is best to employ them immediately after they have been prepared.

*Sensitizing.*—When the production of a heliochromic print is desired, the sheet is immersed in a bath of water containing a few drops of a solution of mercury in nitric acid. I do not indicate the proportion of mercurial salt, the degree of concentration and the purity of the nitrate of commerce being very variable, so that the amount employed must be increased or diminished according to circumstances. If the proportion employed is too little, then the image produced will be a negative; and if, on the contrary, it is too much, the colours will have less vivacity. A few preliminary essays will soon give precise indications of the quantity which it is necessary to employ.

In any case, however, it is necessary to filter the solution to eliminate the basic nitrate which becomes precipitated in the vessel in which the mixture is made.

(To be continued.)

## THE PHOTOGRAPHIC SOCIETY.

THE meeting of Tuesday evening was a singular contrast to that held a month previously, in the same room. With the exception of some short sharp passages on the legality of various courses—which the chairman adroitly put aside by ruling that as no individual opinion could decide such legality, they would proceed in that course which seemed most conducive to the well-being of the society, and get an indemnity, if necessary, as soon as a legally constituted authority was established—the whole tone of the meeting was one of conciliation. At the outset Mr. Hughes, as chairman, suggested that this word—conciliation—should be the key-note of the evening. Mr. Hooper, in moving his resolution that the late president and officers should be invited to resume office again, urged the exercise of a similar spirit with equal good sense and good taste, and Dr. Mann gave his cordial support. Various of the requisitionists followed in the same tone, Mr. Walter Bird especially emphasising the esteem of those who had been in opposition, on a legislative question, for the council as gentlemen, and their appreciation of their services to the society. The resolution inviting the return of the late officers was passed with unanimity and cordiality, as was also the especial vote of thanks and the tender of a medal to Mr. Glaisher, as president. As we have not shrunk from the task of commenting with the utmost frankness on what we conceived to be the false steps of the requisitionists, we feel bound to express with equal frankness our conviction that every effort was made, in fact and in spirit, to disavow any lack of confidence in the president and council, and to remove any feeling of slight or discourtesy which former proceedings, in which it was admitted great excitement had prevailed, might have engendered.

The issue remains to be seen. We are unable to say how far these overtures will be accepted. The council, which knew so much better than any one else could do the unremitting labours of the president on behalf of the society, and his perfect loyalty to it as a society; that council who heard from the president's lips, on the first intimation of disaffection existing in the society, the assurance that, as he was president of the whole society, and not of any mere section of it, the grievances—real or imaginary—of any member of the society should receive his honest attention; the council which knew all this placed their official honour in the president's hands, to remain or retire with him; and they will of necessity, with equal readiness, act with him in relation to the resumption of office. We are unable to speak for him; but as we

have repeatedly heard him remark, in relation to recent questions, that interest of the society took precedence in his mind of any merely personal considerations arising out of these discussions, we conceive it to be probable that the society may again meet under his able presidency. In private life, if one gentleman having given occasion of offence to another hasten at their next meeting to disavow the intention of offence, and make the *amende honorable*, but one course, as a rule, remains, and that is to accept the disavowal, and resume a cordial understanding. We must confess to a hope that a similar course may be followed by the body of gentlemen concerned in the recent antagonism. We know that many of the gentlemen on the council, who have worked very hard for the society, are really anxious to retire and rest in the privileges of private membership; but as their resumption of office for the remainder of the session will possess the public significance of restored harmony, we cannot help expressing a hope, whilst we feel no right to urge our views further than is implied in such expression, that the overtures of those in opposition, of those who supported the council, and of the independent members, all combining in the unanimous vote of Tuesday evening, may not prove unavailing in securing the restored harmonious activity of the society.

## THE PROPOSED NEW LAWS OF THE PHOTOGRAPHIC SOCIETY.

THE revised code of rules prepared by a committee appointed at the February meeting of the Photographic Society is now in the hands of all the members. It is put forth, as Dr. Mann, on behalf of the committee, explained, as a rough draft for consideration, suggestion, and improvement. It has manifestly, however, been prepared with much thought and care, and must have involved much close labour, a special aim to meet any of the complications which late events have shown to be possible being maintained. The great length to which the document runs is somewhat startling, as it comprises not less than twenty-five sections, and nearly eighty clauses. This may be absolutely necessary to prevent the possibility of misconceptions, but we must confess that condensation seems to be desirable, if possible. As we have not, however, carefully considered the details, we here rather express a wish than suggest a possibility. The more numerous the conditions the more difficult it is to understand or remember the precise bearing of each, and the greater the risk becomes of involving unforeseen and unsuspected incompatibilities, some slight suggestion of which was made at the meeting on Tuesday evening.

In the main, the suggestions seem good, and in one or two points decided improvement has been made on the two new laws passed at the special meeting a month ago. The president, for example, is, in these rules, to be elected annually, and to be eligible for re-election every year, instead of being bound to retire at the end of three years, as in the rule passed a month ago. The treasurer and secretary are in like manner to be eligible for constant re-election, instead of being, as before proposed, bound to retire at the end of three years. In regard to the council, retirement by seniority, and ineligibility for immediate re-election at the end of three years, remain in the proposed new rules, and will constitute, we still think, as we before pointed out, an element of weakness, as rendering the necessary continuance in office for three years of officers who may, for various reasons, prove inefficient; and the imperative loss, at the end of three years, of officers, however able, experienced, and efficient they may be. Whether the advantages to be gained by a regular and methodical change in the constitution of the council will compensate for these disadvantages is, of course, a question open to discussion.

The most important addition to this code is a provision

for giving election suffrage to country members, in character something very similar to that we proposed some weeks ago. In engraving this plan on to their project we think the committee have done wisely. But there still remains an important omission, which is, we think, the result of an oversight. There is no provision that we can find for the voting of country members on questions such as those which have recently been agitating the society. In the matter of elections provision is made, and balloting papers are to be sent out to all members, who may give effect to their wishes by duly marking such papers and returning them to the secretary; but on all other subjects—questions of alteration of law, for example—no such provision is made, and the new laws are altogether silent on the mode of voting on such matters. One sentence copied from the old laws implies, indeed, that personal voting only can be permitted in cases in which the ballot is not absolutely specified, as in the matter of elections. In the seventh section, clause twenty-four, it is enacted that members shall have the right to be present, and vote on all questions. This was the only clause in the old rules which seemed to exclude absent members from voting on all important questions by means of balloting papers. As on this point we apprehend there can be little difference of opinion as to the propriety of giving a voice to the entire society in any question of such weight as the alteration of the laws, it is only necessary to commend the matter to the consideration of the extended committee.

This brings us to another point of some importance. In adopting a new code of rules making extensive and important changes, it is surely desirable to secure the unanimous voice of the society, if possible. Surely some provision should be made for taking the vote of every member, whether residing in London or the provinces, whether able to be present at a meeting or not. The committee of the members generally to be held in a few weeks—in a fortnight, if convenient—will, of course, simply consider the subject; but before any final steps are taken, and when a satisfactory code shall have received general assent from a meeting in London, we trust the code will be submitted to the vote of members generally before it receives the force of law.

#### ACETATE OF LEAD FOR REMOVING HYPOSULPHITE FROM PRINTS.

“WILL the use of acetate of lead in the final washing water prevent the fading of prints?” The question has been asked of us some scores of times since we published Mr. Newton's suggestion a year or two ago. Our uniform answer has been to the effect that experience alone could determine. The experience of a committee in America, just recorded at a meeting of the German Photographic Association in New York, appears to be unfavourable. Here is the record, for which we are indebted to our friend Mr. E. L. Wilson:—

“When Mr. Newton, over a year ago, published his process of removing the hyposulphite of soda in the prints with acetate of lead, a committee was appointed to test this method thoroughly. Said committee reported at next meeting that the prints were, indeed, free from all hypo, but that the tone had changed a little from brown to blue. At the same time, fears were expressed that the new chemical combination would in time injure the prints. This has proved, now, to be only too true. The secretary, who was chairman of the aforesaid committee, subjected at that time several prints out of one day's printing to the acetate of lead washing, and kept these, together with other prints of the same lot, but washed in the usual manner. At the last January monthly meeting those prints were exhibited, and showed that those treated with lead were bluish-yellow, and very much faded, whereas the others had lost nothing of their original brilliancy.

The meeting thought it very desirable that other associations or individual photographers should publish their experience in this matter.”

#### THE REQUISITIONISTS ON THE ACTION OF THE LATE COUNCIL.

THE number of the Society's Journal published in advance of the usual time, to which we referred in our last, was issued a few days ago. It is chiefly devoted to a reply from, or on behalf of, the requisitionists, as for distinction we are compelled to style them, to the report of the last meeting, and the comments thereon, in the February number of the Society's Journal. When a spirit of conciliation has been manifested, we would not willingly use one word of reerimination; and passing without comment the animus which characterizes this reply, which was manifestly written before the conciliatory idea was dominant, we very briefly indicate one or two errors and misconceptions which it is important to correct.

We shall not again follow this article through the story of the requisitions in which the council is again credited with obstructiveness and with a desire to over-ride the requisitionists, and the provision upon which their request was based, beyond giving the simple and positive assurance that they who believe this statement are utterly mistaken in their estimate of the spirit and action, the aims and opinions, of the council. Neither in the council as a body, nor in the individuals composing it, have we ever heard of any indisposition to modification of the laws, or to the fullest discussion of the need for such modification. The sole complaint of the council is that the requisitionists seem from the first to have credited them with antagonism, and themselves to have assumed a position of antagonism. It is evident that a very dangerous mistake was made, and we earnestly hope that the misconception and its consequences are past. We omit the correction of some other trivial details in this rejoinder, because the mere discussion of their erroneousness might again evoke bitter feeling.

There is, however, one statement made in this rejoinder, which it is most important to correct. We quote it as it stands in the Journal just issued. It runs as follows:—

“The acting council assuredly believe that if the amendments had been accepted, a revised code of laws already prepared beforehand in all their details by the party of the old council would have been brought to the committee. If such were really the old council's plan, that is a somewhat important corollary to the proposal that six members of the committee should be appointed by members.”

The assured belief here expressed, is an utter mistake: it has not a shadow of basis in fact. No attempt to prepare a revised code of laws had been made. Two new rules, giving the fullest voting powers to country members, and much more comprehensive and liberal in spirit than those of the requisitionists, had been prepared as an amendment; but it was felt to be wiser and more conciliatory to propose a general revision, with the co-operation of the requisitionists, and hence the council's proposition.

But suppose such a code of rules had been prepared, and brought to the committee, seeing the requisitionists would have numbered six, and the nominees of the council three, if a dozen codes had been brought ready prepared, the requisitionists had the power in their hands by being able to outvote anything of which they disapproved. But discussion on this and other similar points is fortunately no longer necessary, and we can only hope that whatever the issue of the temporary convulsion in the society, no permanent bitterness may be suffered to remain.

#### PERMANENCY IN SILVER PRINTS.

THE old question, and the old uncertainty. Why do silver prints fade? Is it from imperfect fixation, imperfect washing, or the unstable material of which the image is formed? The answer is, probably, all three—at times

separately, at times in combination. As we have often said, we believe it is less due to imperfect washing than to other causes. The use of a lead salt to remove hyposulphite and dispense with the necessity of perfect washing appears, as will be seen from another article, to have proved a failure. If, as we have often urged, the mischief is most frequently due to action set up in the fixing bath, a plan suggested in the last number of Anthony's *Bulletin* is worth attention. Referring to some prints which had remained pure during various vicissitudes, the Editor says:—

"The only peculiarity in the management of these pictures was that a little air-slaked lime was diffused through the hypo. solution before the prints were put in it. This removed any uncombined sulphurous element, and prevented the formation of a sulphur compound of silver in the whites. If the cause of fading be the free hypo. left in the paper, that can be eliminated by the use of some solution containing a salt which by double decomposition forms an insoluble compound with the sulphur of the hypo. Those easy of acquisition are the nitrate of lead, nitrate of barium, and nitrate of lime. A great deal of evidence has accumulated in favour of the lead salt, and we have been and are surprised, considering the importance of the matter, that so little experiment seems to have been made in this direction."

The most recent evidence respecting the lead salt for removing hypo from the print appears to be altogether unfavorable; but the application to the hypo solution of a substance which unites with any uncombined sulphurous element appears to be free from objection of every kind, and is well worthy of further adoption. We add general details of the printing operations described as successful in the article in question:—

"In our practice we proceed as follows. Our silver solution runs from 30 to 40 grains of nitrate per ounce of water. To this are added a few drops of liquor ammonia, and the solution is shaken and allowed to settle clear. After being decanted, a small quantity of alum is added, and the solution poured into a dish for use. The paper is floated one minute, dried, fumed with ammonia about ten minutes, and printed. A washing bath is prepared by adding to each quart of water used, one drachm of acetic acid No. 8 (if pure). The prints are first placed in this, and left to soak about fifteen minutes. By the combined action of the ammonia still left in the paper and the acetic acid, the nitrate of silver is converted into the acetate, which remains in the water. The prints are subsequently rinsed (only) in two changes of water, and are then placed in the toning bath. It is not necessary to describe the toning bath, because by the acid treatment above described any properly made alkaline bath will answer perfectly well. After toning, the prints are placed in a tank with a small quantity of water. After the toning is finished, the prints are gathered in a mass and left in that state until next day, when they are fixed. After fixing, they are distributed in five large tanks. In these tanks the water enters at the bottom, rises through the mass of prints, and passes off at the top, descending through a pipe to the bottom of the next tank, and so on. The tanks are first filled independently twice, and the entire water drawn off twice. Then the water is allowed to run. We find that water running in this way three hours removes the hypo, so that by the starch test it cannot be detected. As a consequence of this mode of working, we are able to say that we never have faded prints, and never now have yellowish whites. It will be seen that in our practice we do not use the lead, lime, or baryta salts. The reason of this is that we wish to avoid too much handling of the prints, as the salts spoken of should be diffused through the water, from which the prints would necessarily have to be first removed. The above remarks apply of course only to prints likely to be affected by hypo left in the paper. It remains to be learned whether prints from which all the hypo, as indicated by the starch and iodine test, has been removed, do fade. If they be found to fade, investigation should be directed to the possible cause."

#### DRY PLATE DEVELOPMENT.

BY CAPTAIN ABNEY, R.E., F.R.A.S., F.C.S.

I was long under the idea that in order to be successful with alkaline development the addition of bromide was an essential, in order to avoid fogging of the image.

I have lately been practising the dry plate process I de-

scribed in the YEAR-BOOK, and have come to the conclusion that not only is such an adaptation not necessary, but is absolutely hurtful. I do not mean to say that with all processes this is the case, but that, in my process, where extra albumen or gelatine is used as a preservative, even though it be washed off after application, such addition is unbeneficial. Colonel Wortley (whose strong alkaline developer is, to my mind, the greatest advance in photography of the present day) has, I believe, arrived at a conclusion very similar; in fact, I have seen him develop his most sensitive plates without any bromide, merely adding glycochine. In the matter of albumen plates, the organic matter is already supplied; hence the addition of the glycochine with these is necessary.

I must here, however, state that, in my view, negatives are rarely of the highest class unless they be redeveloped with silver. There is almost always a something, nearly indescribable, wanting to give a negative the proper finish, if the whole of the density be procured by the alkaline method. It will be, therefore, readily seen that my previous remarks must be received with this proviso.

Bromide is not a restrainer or a retarder; it is a destroyer of the latent image; and I am convinced that the stronger the developer used, the less necessity there is of its employment. Gelatine or albumen, on the other hand, are controllers (not in the military sense, luckily). The development is only prolonged by their presence, and is thus brought under the control of the manipulator.

I should like to recommend those interested in dry plate work to try the following developers:—

- 1.—Pyrogallic acid (best English) ... 12 grains  
Water ... .. 1 ounce
- 2.—Liquor ammonia ... .. .880

Flow over a dry plate—such as I have described—enough of No. 1 to cover the plate; add to the cup one or two drops of No. 2; mix thoroughly and apply. The image will appear by degrees, and as development seems to flag another drop of No. 2 may be added till all detail is visible. Neutralize with citric acid and water (1 to 50) and redevelop with silver till printing density is obtained. The difference in exposure necessary for this development, and that necessary for development with weak ammonia added, has lately been brought home in a practical manner. Some of my men have been exposing plates for four minutes, using one drop of a five per cent. solution of liquor ammonia. With one of the same batch of plates I gave twenty seconds (less than I should have given a wet plate) and developed as above, and got a picture more brilliant and full of detail, and *no fog*. Fog is almost unknown by any of those using this development.

#### ON A NEW STUDIO.

BY SAMUEL FRY.\*

I MENTIONED last week that I would continue in the present number of the NEWS with a description of certain internal details which, though not so directly and immediately concerned in the production of pictures, are too often overlooked. As a rule, studios are unendurable during the heats of summer, and in winter the means of warming are very insufficient. In the building I am describing, during extremes of temperature out of doors, it is about the pleasantest room one could wish to inhabit. For ventilation during summer an opening two feet square is placed in each angle of the gable, with louvre boards moving by a cord. These openings being opposite to each other, the heated air is rapidly swept away without draught below. At the same time the side lights lift completely out, and during many months of the year are only replaced at night, and taken out each morning. During the extreme heats of last summer the room was the coolest place to be found. A similar system is applied to the developing room, where, under the sink, a large door opens

\* Continued from page 87.

to the outer air, being so arranged as to exclude light. A ventilating shaft opens immediately at the side of the sink, and causes a current to another at the top. All this is done without causing an unpleasant draught of air, and fumes of collodion and other chemicals pass off at once.

I look upon these as important matters. Many photographers suffer severely from impaired health, as I have done; and until this arrangement was made I was for some years rarely really well. I commend it earnestly to my fellow-workers.

And now with regard to warming in winter. A number of articles appeared lately in this journal advocating various systems of raising the temperature, but each of these was only suited for acting on one room, and appeared to cost almost as much for that as should have been required for a suite of business rooms. Every one must have studio, printing room, painting room, mounting room, and dressing room at least; and those in anything like an extensive way of business have many more. The most equal temperature is obtained, and only one fire required, by circulating pipes. In my own case, ten rooms are heated with 300 feet of pipe for thirty shillings per month. This is done without dust or trouble. In the studio is a cupboard through which the pipes pass for warming baths and developing solutions, drying negatives, and other purposes. During winter the baths are placed here at night, and in the morning are found at a good working temperature. In the developing room the pipes have a grating, on which the camera-slides, after wiping, are placed, and kept thus in good dry condition. The developing room should not be used as a laboratory; chemical operations are better done in a special room, thus leaving baths and solutions always ready for use. I like an abundance of light in the developing room, and a sliding yellow window, which, when open, leaves white ground glass for examining negatives against. On a shelf over the range of baths in use are grooved boxes fixed, and which hold the various sizes of plates. They are all albumenized and placed in the boxes, coated side downwards, thus avoiding dust. Those who once try this will not depart from it. Close at hand, in the developing room, is the mouth of the speaking-tube, by which I receive information from those who attend to sitters; and I can also, by a code of signals, communicate with the printing and painting rooms. This power saves much time just at the moment when time is valuable.

In all these arrangements my idea has been to enable me to get through with sitters in the most efficient and prompt manner. Good pictures are generally done quickly: one of the best men in England can take three poses of cards—two of cabinets, and a ten by eight picture—in twenty minutes. This is what it should be. All should be ready when sitters come, and no occasion for hurry or excitement, nor yet for keeping punctual people waiting.

### LIME CYLINDERS FOR THE LANTERN.

BY JAMES MARTIN.

ABOUT twenty years ago, when residing in the city of Exeter, it was my good fortune to meet with several highly intelligent and ingenious workmen in various branches of handicraft, by whose assistance I succeeded in carrying out several scientific experiments; amongst others was an attempt to make cylinders for use with the hydro-oxygen light without the troublesome, tedious, and sometimes dangerous process of turning and drilling them in the lathe.

An experienced exhibitor having once told me that when his stock of limes happened to be exhausted, and time pressed, he made a practice of using a bowl of a tobacco pipe as a substitute, the idea occurred to me that serviceable cylinders might be formed of pipe-clay, which might

be kept any length of time without injury, and be capable of resisting rough usage. According to my design, one of my workmen turned me a mould of box-wood; taking this to a tobacco-pipe maker, in a few days I received several cylinders, seemingly all that could be required. On trying these in the lantern, I found no perceptible difference in the light, but upon examination I observed that they pitted rather deeply and sharply, and that a tear of vitrified substance had exuded from the hole. Upon my reporting this to the pipe-maker, he said that he could easily obviate that by the addition of a little more grit to the composition of which they were made, and promised me some that would prove all I could desire. Business calling me just then to a great distance away, and having, in the meantime, found that serviceable cylinders could be easily made from common chalk (the method of doing which I gave to your readers some time since in one of my articles on the magic lantern) I allowed the matter to drop.

The ingenious experiments of Mr. Gilmour recall the whole to memory. As he invites suggestions, perhaps he will allow me to say that the coarser kind of chalk, containing more caustic lime than the finer, is no doubt the cause that they form the harder cylinders.

I would suggest that his next composition should be made as follows:—Taking a knob of white lime, let him place it in a colander, and pour sufficient water over it to damp it. In a little time it will fall into a fine powder; this is hydrate of lime, of which the mason makes his mortar. I need not say how hard this becomes when dry. I should also advise that the calcined magnesia should be used in preference to the carbonate, as containing a much greater proportion of its metallic base. It would be interesting also to submit some of the cylinders to the process of firing and annealing in a pipe-maker's oven.

## Correspondence.

### GELATINO-EMULSION TRANSPARENCIES.

DEAR SIR,—From the many enquiries I am constantly receiving for information as to the *modus operandi* in producing the transparencies now seen by many, and as I really have not time to answer all letters sent me on this and sundry other matters connected with the gelatino process, and as my answers will equally apply to all who are interested in this process, perhaps you will kindly insert this for the benefit of all.

The transparencies I have made during the past winter have all been done by contact, the exposure ranging from one to three seconds by daylight, and from five to ten seconds by a gas flame. The time depends entirely on the density of the negative and the amount of light at the time of exposure. In all cases the exposure should be as short as possible, or the most satisfactory results will not be obtained. Trying a plate or two I exposed yesterday, I find the light is getting strong. I gave one second, or as quick as I could expose, and they were fully timed. The developer is the same as directed in my instructions for plates generally, with a little more strengthening or intensifying than usual, as they lose a little in the clearing out, and by which you get the parts unacted on by light as clear as the glass itself.

If a rich black is wished, proceed as follows:—Drop into a glass measure four or five drops of a fifteen-grain solution of gold in one ounce of water, and flood the plate with it until the desired colour is obtained. Wash thoroughly, and pour over the following mixture: cyanide of potassium, ten grains; water, one ounce (this can be made in quantity, as it keeps for some time), to which add a few crystals of iodine, until it will, on shaking well, take up no more; then add a little more cyanide, to have it in slight excess of the iodine. Pour on a little of the above, and you will very soon have a clear transparency. Wash well, and dry spontaneously.

A question put to me repeatedly is, what advantage do you claim over the present processes in use? My reply is, simplicity,

cleanliness, and economy; and with this I shall leave the matter in your own hands, as I herewith enclose a small packet of the pellicle to test, for yourself, and shall be pleased to know the result, good, bad, or indifferent. As, at times, our greatest failures lead on to our greatest successes, I am as anxious to hear of failure as success.

In conclusion, allow me to thank all those gentlemen who have so kindly wished me success.—Your very obedient servant,  
R. KENNETT.

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

THE adjourned general meeting of this society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, March 10th.

MR. Jabez HUGHES took the chair, and explained that, this being an adjourned meeting, he had been requested to take the chair in continuation of the position he held in the meeting a month ago. Before the minutes were read he wished briefly to refer to some matters connected with the meeting last month, in which some excitement, and possibly bitterness, prevailed. He hoped that during the time which had elapsed these feelings had subsided, and that at the present meeting everyone would realize the full force and value of the key-note which he wished to sound at the outset, and which would be found in the word "conciliation." (Applause.)

MR. F. HOWARD, acting as secretary to the council, proceeded to read the minutes of the special meeting.

MAJOR MALCOLM, on the chairman's appeal as to whether he was to sign the minutes, proposed that the subject be postponed until that day six months, a parliamentary process with which the meeting was perfectly familiar. Without being a frequent attendant at its meetings, he took a deep interest in the society, and had been much pained by the record of the proceedings at the last meeting. Much strong feeling had prevailed, and there had been already, as he conceived, a too hasty rush into print, and probably there was much of the record of the proceedings which, on mature consideration, it would be found a good thing to have removed. The attack on the president and council—

MR. GREENWOOD rose to order.

THE CHAIRMAN suggested that Major Malcolm would have an opportunity of raising any question he wished at a later period. The only point at present was the question whether the minutes read were an accurate record of the proceedings.

CAPTAIN ABNEY said that the confirmation of the minutes was equivalent to the third reading of an Act of Parliament, and gave the force of law, which, till confirmed, they did not possess.

THE CHAIRMAN said that they had taken the opinion of various lawyers, including two Queen's Counsel, and all decided that the confirmation of the minutes simply implied an acknowledgment of their correctness, and had no effect on the legality of the proceedings; that legality depended on the proceedings themselves, and was quite independent of the existence of minutes at all.

CAPTAIN ABNEY said there would be no difficulty in getting the opinions of a dozen Queen's Counsel to precisely the opposite effect.

AFTER some further discussion the question was put to the meeting, carried, and the minutes confirmed.

MR. HOWARD then read the minutes of the annual general meeting, which having been confirmed,

THE CHAIRMAN said the next business was the election of officers to fill the existing vacancies. The gentlemen in office at the last meeting had felt that the proceedings implied a want of confidence, and had resigned their offices. They had not, however, resigned their membership of the society, and, being members of the society, were as eligible as any one—probably, for many reasons, more so—for election now. A gentleman present had given notice of a motion in which he would propose that the same gentlemen who held the offices should be again elected to fill them. Speaking as a member, and, he believed, expressing the feelings of many with whom he had worked, he would say there was no objection of any kind to these gentlemen. The difference which had existed did not imply any objection; it was merely a difference of opinion as to the proper mode of election. He believed that the acceptance of this motion would be the best and wisest thing which could be done, and one peculiarly fitted to heal any difference or breach in the society. The resolution of

MR. HOOPER was to the effect that the president, vice-presidents, treasurer, council, and secretary be again requested to take office for the remainder of the session, all officers being elected at the next annual general meeting in accordance with the new laws about to be framed.

COL. WORTLEY rose to order. He asked if it would not be necessary to re-elect all the officers of the society?

THE CHAIRMAN said, no, only those to fill the vacancies caused by resignation.

MR. HOOPER felt great satisfaction in hearing the chairman give, as the key-note of the evening, the word conciliation, and would try to maintain it. When, at the last meeting, Dr. Mann distinctly stated that the proceedings of the requisitionists were not intended in any sense as a vote of want of confidence, he had suggested that some steps should be taken to give effect to that avowal. Nothing would so effectually do so as to re-elect the same officers. As an independent member, belonging to neither party in this difference, he felt that he could with propriety urge this as a step having the good of the society, and not of any party, for its object; and in urging it upon them, he did not plead for a majority simply—of that he felt quite satisfied; but he earnestly urged upon every member the importance of unanimity in a vote asking the return of their officers to take charge of the society through the period of revision, for they could hope to do little else this year; and he hoped that the changes would in every respect make this society the national society of Great Britain. He asked that the vote should be given unanimously, with that dignity and grace which could best give it value, and that henceforth the society would work in perfect harmony to the benefit of all its members and of the art it represented. (Applause.)

DR. MANN had great pleasure in seconding this motion, and giving it his support. He hoped that the old officers would again resume office, and aid in guiding the society as in the past.

COL. WORTLEY moved an amendment to the effect that a certain number of the old officers be elected, and some other gentlemen, whose names he substituted, for some of those of the old council.

THE CHAIRMAN pointed out that a greater number of names had been proposed than the vacancies.

COL. WORTLEY stated that all the officers of the society required election now, as he contended that there were none in legal existence. As the chairman had taken legal opinions, he might mention that he also had taken legal opinions, which left no doubt that the proceedings of the last meeting were illegal. He had now suggested a means of retrieving the position by an entire new election. If they declined, the consequences must be on their own heads.

THE CHAIRMAN said that for the present they must consider the proceedings legal and valid. If they were not so, disintegration of the society must follow. To save the society they would risk assuming the legality of their proceeding, and when they had a council fully and legally formed, they would ask for an indemnity for any proceedings the legality of which might seem legal, but which were taken to secure the position of the society.

AFTER some confused and conversational discussion, in which many members took part, Col. Wortley withdrew his amendment.

A motion to elect the old council individually seriatim was also made, and after some discussion withdrawn.

COL. WORTLEY then proposed that Dr. Diamond be added to the council.

MR. SPENCER urged the adoption of Mr. Hooper's motion as tending to the restoration of harmony.

MR. SAWYER also supported the same motion as a means of securing harmony, and doing it in a graceful manner.

MR. WALTER BIRD regarded the motion as one both of policy and of loyalty to the society. He had joined in the late proceedings because he was opposed to the views of the late council in relation to certain points of legislation; but he was not opposed to any of them as men. Indeed, he doubted if better men could be found in the society for the position they had held. Looking at their executive operations, it must be fully admitted that they had managed the affairs of the society with energy and success, and had brought it through a period of considerable difficulty, from a state of pecuniary deficiency, to one of prosperity and success. The loss of many of them would be a considerable loss to the society. He certainly hoped that they would be re-elected as a body as the most delicate and graceful mode, securing reconciliation and future harmonious working.

CAPT. ABNEY said that in the course of the discussion such questions evoked, hot words were apt to be spoken on both sides. He wished, however, to disavow the slightest personal feeling to

the requisitionists. He thought that another and wiser course might have been taken by them, but that he did not now wish to discuss; he simply, in speaking for himself—and he thought he represented many who had acted on the side of the council—wished to disavow personal bitterness, and for himself, if he had spoken hot words which had pained anyone, he withdrew them.

After some further conversation, the vote for the return of the council in a body was put and carried, amid considerable applause, unanimously, with one exception—one hand was held up in opposition.

The CHAIRMAN said that as the election of the six officers at the last meeting had been effected in the midst of much excitement and feeling, they now wished to resign their offices into the hands of the meeting, so that their places could be filled by the meeting. As there was nothing of pique or feeling in this step, he might state that they would serve again if re-elected.

Mr. REED moved that the six gentlemen who had taken office in the emergency of the society be re-elected.

Mr. SPILLER, as senior vice-president, but without pledging his fellow-officers to any course in this matter, had pleasure in seconding the re-election of these gentlemen.

The resolution was carried unanimously, as was also a vote of thanks to Mr. Bird for having accepted temporarily the office of treasurer.

Mr. SEBASTIAN DAVIS proposed that a vote of thanks to Mr. Glaisher for his past services as president, together with a silver medal, should be presented to him.

Mr. WENHAM seconded the resolution, which was carried unanimously amid considerable applause.

Some general discussion on the draft of the new laws followed, the chairman suggesting that the gentlemen to have been nominated by the late council be now added to the committee, as the best carrying out of the spirit of harmony and conciliation.

Mr. STILLMAN thought that the laws had better now be handed over to the council generally for their consideration and suggestion.

Mr. WERGE objecting to the confusion this might cause.

Dr. MANN pointed out that at present the rules sent out were merely a rough and ready draft for improvement.

Mr. ACKLAND and Mr. GREENWOOD made suggestions as to details.

Major MALCOLM pointed out the danger of hasty decision, as the work of securing laws harmonious in themselves and efficient in working, required much care and thought. There was, he thought, room for improvement yet in those sent out.

After further discussion it was resolved to bring the draft, at a speedy date, before a committee of the society, the time of which would be duly announced; a fortnight from the date of the meeting being mentioned tentatively. After a vote of thanks to the chairman the proceedings terminated.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this society was held in the Hall, 5, St. Andrew Square, on the evening of Wednesday, the 4th, Mr. R. G. MUR, president, in the chair.

The minutes of previous meeting were read and approved, and Messrs. D. Dalgleish, James Allison, George Lisle, J. C. Hay, R. Menzies, Alex. Sutherland, and Thomas Pringle were admitted ordinary members.

Mr. ALEXANDER HENRY said that it was, perhaps, not much in the shape of honour that the society had to bestow, but he understood that it had from time to time done what it could by electing as honorary members those who had made their mark in the annals of photography. He had, therefore, much pleasure in proposing that the name of Captain Horatio Ross, of Wyvis Lodge, Rosshire, be added to the honorary list. The world generally knew something of what Captain Ross could do with his rifle, but photographers knew that he was equally at home with the camera, and that, too, in a line that was, from its difficulty, not often attempted, namely, the photographing of deer in their native haunts. Some of the members had recently had an opportunity of seeing specimens of his work in that department, and he was quite sure that they would agree with him in saying that they were such as would do credit to any photographer. Captain Ross, he said, had been a pioneer in the art, and, while honouring him, the society would be doing honour to itself in electing him as one of its honorary members. The motion was seconded by the secretary, Colin Sinclair, and carried by acclamation.

It was proposed and carried the same way that Mr. John Peat,

who had been an active member of the society from its foundation, and who had removed to London, be elected a corresponding member.

The next business was a discourse on the Polarization of Light, with illustrations, by Mr. W. Gilmour and Dr. John Nicol. Dr. John Nicol began by saying that he thought it necessary to apologize to the society, not for bringing the subject of polarized light before them, because, although he was not as yet prepared to connect it in any way with the practice of photography, no one could say how soon such a connection might be discovered. Photography was gradually passing out of the domain of empiricism into that of an exact science, and whenever the transformation was complete, he had no doubt that a knowledge of polarization, as well as of everything else connected with light, would be found useful. Neither did he need to make an apology for Mr. Gilmour, as they would very soon see that he had not only a stock of apparatus for the production of the most beautiful illustrations, but that he knew very thoroughly how to use it to the best advantage. The apology, therefore, was for himself; and what he honestly felt was, his presumption in coming before them with his very limited knowledge of such an abstruse subject. He, however, felt it due to himself to explain why he had undertaken a duty which he considered himself unfit for. Some months ago he had been at a meeting of the Pharmaceutical Society, at which Mr. Gilmour read a paper on polarized light, accompanied by a series of very fine illustrations; and he thought it would be very desirable to get it repeated to the members of the Photographic Society. When he, however, called on Mr. Gilmour, he found that gentleman's modesty standing in the way, but he (Mr. Gilmour) offered to conduct the experiments on condition that he (Dr. Nicol) would undertake the description. "In this way," he continued, "I was led into undertaking the work, not because I thought I could do it properly, but because it seemed the only way by which the very fine illustrations could be seen by the meeting." He then said that the wave or undulatory theory was now almost universally accepted, and started with a description of what he called a fundamental principle, the doubling of the intensity of a wave when two half undulators were evenly superposed, and the interference producing darkness when they met unevenly, in consequence of the trough of the one fitting into the ridge of the other. The spectrum was then placed on the screen, and the principle of refraction explained and illustrated. He then explained the laws of reflection, and called special attention to the fact that, when a ray falls on a plate of glass at an angle of between  $56^{\circ}$  and  $57^{\circ}$ , one portion is reflected and another refracted, as at other angles; but at that particular angle which is the angle of polarization for glass the refracted and reflected rays are found to possess different properties; so that if the refracted ray is allowed to fall on another plate at a like angle, it will all pass through, and none be reflected; and in like manner the reflected ray, if sent to a plate at a like angle, will all be reflected, and none pass through. If, however, the second plate be turned one quarter of a circle, and the same angle be maintained, then the reflected ray will be refracted, and *vice versa*. This, he explained, was polarized light, and the phenomenon was accounted for by supposing that the undulations were propagated in various directions, or planes, say in horizontal and perpendicular. When the undulations fell on a plate of glass, those that were in the plane of the structure of the plate passed through, while those that were at right angles were reflected. In this way the refracted waves, being in one plane, would pass through the second plate if its structure was parallel to the first, and be reflected if it stood at right angles. After describing the construction of the lantern polariscope, he went on to show that certain crystals which were of unequal density possessed the power of double refraction, or of separation of the light into two planes of polarization, and illustrated it with a rhomb of Iceland spar, which separated the rays into two discs on the screen, and when the discs were caused to partially overlap each other, and a plate of selenite introduced, the composition of white light by a colour and its complementary was beautifully shown. After showing tourmaline, and several other natural doubly refracting crystals, he explained that doubly refracting properties could be artificially given to glass by heat, pressure, &c., which was also very successfully shown by Mr. Gilmour. He next called attention to the colours of the soap bubble, and explained that they were caused by the reflections from the outer and inner surfaces of the exceedingly thin medium meeting at such positions as that the green and violet should by interference produce darkness, white and red should be doubled, and so on with all the rays. In this way, he continued, when a plate of selenite is interposed between the polarizer and analyser, by its doubly refracting power

it bifurcates the polarized ray, which, in passing through the latter, is split up into the three coloured undulations of which it is composed, two of which, by interference from the cause previously explained, neutralize each other, letting the third appear as coloured light. The interference rays are changed at each quarter of a revolution of the analyser, and so the change of colour is produced. Mr. Gilmour then introduced a series of unannealed glasses with fine effect, followed by a number of slides of crystals of morphia, salaric, borax, &c., &c., and finished up with some plates of selenite, cut so as to represent roses, tulips, pansies, &c., &c., which elicited much admiration.

Mr. TURNBULL then reinstated his improved lamp for the lantern or sciopticon, and showed that he had overcome the objectionable dark line over the screen. The lamp, as will be remembered from the report of the last meeting of the society, contained three wicks, and gave a decidedly brighter disc than that supplied with the sciopticon, while the dark line complained of then was altogether wanting when the lamp was slightly angled.

Votes of thanks were then given to Messrs. Gilmour and Turnbull and Dr. Nicol, and the meeting adjourned.

## Talk in the Studio.

**LECTURE ON PHOTOGRAPHY.**—A lecture on photography was delivered in the Congregational School-room, Kyle, last week, by Mr. Arthur Debonham, who gave an interesting historical and descriptive account of the art, and illustrated it by experiment.

"THE PICTORIAL WORLD" is the title of a new weekly journal, which promises to be a valuable addition to periodical illustrated literature. It sends out a capital first number, with a very fine rendering in wood engraving of one of Messrs. Robinson and Chorrill's charming studies of childhood.

## To Correspondents.

**W. JONES.**—You should have stated the details of your mode of working your collodion transfers, and we could better have aided you. Is the image toned, and how? Judging from the general appearance of the print, it has been fixed in oil hypo saturated with silver salts, and imperfectly washed, leaving some of this hypo in the film. This would cause a result similar to that you send us.

**CANCER.**—Lithographic ink, with modifications to suit conditions, is used in photo-collographic printing. We presume that some such firm as Hughes and Kimber would supply it; but as it does not come strictly within the scope of our experience, we cannot say with certainty. 2. We do not quite understand what you mean by "binding down the edge of Waterhouse plates." 3. Captain Waterhouse has described from time to time different experimental modifications, but each formula must be taken by itself, and not necessarily as a condemnation of the whole, or some part of another. 4. The addition of nitrate of baryta to the silver bath necessarily causes a slight veil or deposit on the image, especially perceptible in the shadows after development with iron. The process of varnishing will cause this to disappear. 5. We cannot specially recommend any lens or maker in this column. 6. Albumen is always liable to decompose with keeping. Try the dried albumen, which Hopkin and Williams supply. 7. We do not know much of the work of Geymet and Alker. Possibly the paper for Mariotype may be had of Marion and Co., Soho Square.

**PUS (Birmingham).**—If you use a strong solution of chloride of gold in an acid state it will often bleach the image very seriously. When you find this happen, dilute the solution, and add a little chalk to neutralize it. Plate glass is preferable to crown for working the eburneum process.

**AMATEUR.**—As a rule, and for general purposes, a neutral silver bath is best for printing purposes. An alkaline bath has some advantages in sensitiveness, but it is apt to dissolve the albumen and to get discoloured. The prints you enclose are suggestive of somewhat flat, fogged negatives, and if this is the case it would account for slow printing and weak, flat results. So far as you describe your printing operations, they do not account for the faults of the prints. We should, however, use a forty-grain bath, and until you have gained some experience avoid experimenting with such additions to the bath as alum.

**ACETIC.**—We do not remember the address for which you ask.

**CELUI-CL.**—By a powdery collodion is meant one which gives a powdery film in contradistinction to one which gives a horny, tough film. We cannot say certainly that any commercial sample will always possess that quality. That you mention is rarely so when new. Most samples acquire that character with age, although some have it from the first. This is a point upon which you will have to rely upon your own discrimination and observation.

**DEAF-AND-DUMB ARTIST.**—You will have seen that the formula appeared. It stood over for a week or two owing to the pressure upon our space.

**COL. BATCHELOR.**—Mr. Manners Gordon is not in England at present, and we are uncertain at the moment of his address. We will forward the letter when he returns.

**R. J. L.**—Various forms of press have been tried in photo-collographic printing, and each has some advantages; but we believe that the ordinary platen press, used for letter-press printing, is found to have the fewest disadvantages. 2. The plate requires preparation in rolling up, much the same as a lithographic stone. As you must see that at present it is to a great extent a new industry, and that every one must gain his own experience.

**F. B.**—The proportion of water and chloride of gold is not, within certain limits, a question of vital importance in toning. Various printers use from five ounces to ten ounces of water to one grain of chloride of gold. The weaker solution tones more slowly, and does not require watching so closely. The acetate toning bath is not strictly an alkaline bath. The acetate of soda, which is a neutral salt, is decomposed, free hydrochloric acid generally present in samples of chloride of gold in greater or less degree being neutralized, and acetic acid liberated. It is always desirable to rinse prints on leaving the toning bath before placing them in the fixing bath, or otherwise the hypo is apt to be decomposed, and sulphur toning result.

**G. D.**—Your attempt to produce the softened effect which has been named photo-mezzotint has failed because you have printed with diffused light. You must print with direct sunlight, or, failing that, you must place your printing frame in a box, which will cut off any but direct rays. If rays from all directions pass through the negative when it is not in contact with the paper, it is clear that only a blurred mass must result. With direct light, a piece of thin glass answers very well.

**ANOTHER BONA FIDE.**—See report and leader on the subject. There seems to be a probability of the restoration of harmony. The laws you have received are simply a draft for consideration.

**TROUBLED.**—The yellowish brown stains are due to imperfect fixation. You have been using your fixing solution over and over again until it is exhausted and acid; or the prints have stuck to each other whilst immersed; or you have used the solution at a very low temperature. The fixing bath should be fresh, not too cold, should not be acid, and the prints should be kept in motion.

**R. D. F.**—Yes: a weak developer is useful in copying engravings. If you use the five-grain iron solution, add about ten minims of acetic acid.

Several Correspondents in our next.

## The Photographic News, March 20, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO

POLITICAL PHOTOGRAPHS—ANTIQUITIES IDENTIFIED BY PHOTOGRAPHY—ONLY AN AMATEUR—HOW TO RENDER GLASS OPAQUE OR FROSTED.

*Political Photographs.*—Photographers have been getting into trouble in Alsace and Lorraine. Certain pictures have been published, it appears, and exposed for sale in the shop windows of Mulhouse and Strasburg, which the German Government declare to be political emblems, and injurious to the new régime. The precise nature of these photographs has not transpired, but we were informed some time ago that M. Braun's establishment at Dornach, whose beautiful pictures of Swiss and Alsacian peasantry are well-known, was busy publishing in large numbers two magnificent prints representing Alsace and Lorraine. The pictures represented peasant girls, gracefully posed in their national costumes, and wearing a sad face of mourning, which could not be interpreted otherwise than that the country they represented were *en deuil*. They were very fine examples of art photography and carbon printing, and such charming pictures, as a matter of course, found a ready sale at Paris and in the French provinces. We should very much regret to hear that it is these excellent photographs that have roused the ire of the German Government, for although one might purchase such things with a certain degree of sympathy, they would scarcely lead, one would think, to foment any international quarrel, or to embitter the hostile feelings of the anti-German party. These pictures may, however, have led to the production of others, scarcely so temperate, for the complaint made is, that some of the photographs not only represent peasants in national costumes, but have, moreover, a tricoloured cockade affixed to a mourning cap, signifying, obviously, unalterable devotion to the French cause. After all, the publications do not seem very serious, and scarcely warrant the strictures put upon the shop-keepers of the cities we have named, in the form of a circular which has been addressed to all librarians, printsellers, and photographers, forbidding them to sell or expose in their windows any print which may be invested with a political meaning.

*Antiquities identified by photography.*—A colossal stone statue has recently been grubbed up in the vicinity of the Thames marshes, not far from an old point of disembarkation, where Government ships were wont to discharge their cargoes some seventy or a hundred years ago. The statue has been rescued from its inglorious position, scraped and washed, and placed in an upright position upon a civilised grass plot, and now the question has arisen, what is it, and where does it come from? The scornful treatment it has received, both in this country and elsewhere, is plainly shown by the dilapidated appearance it presents, for one can only give a hazardous guess as to the real nature of the work. The stone is said to be Egyptian granite, and the statue, which is of heroic size, standing nine or ten feet high, has been pronounced by a connoisseur to be that of a Roman centurion. But other opinions are desired upon the subject, for it may turn out a valuable piece of sculpture, and the dicta of men learned in the matter, at present residing at Cambridge, Berlin, and Vienna, are sought. Years ago there would have been no alternative but to get the *savans* to come over to see the image, or, if they would not come, then the mass of stone would have to go to them. Now, thanks to photography, a half-dozen large prints, showing the statue from various points of view, demonstrate quite as much, almost, as a careful examination of the work itself. Therefore no great expense need be incurred in regard to its preservation until competent men pronounce, from the evidence before them, whether

the statue is really a valuable one or not. This is one more illustration of the way in which photography steps in most opportunely to aid in the discovery of truth.

*Only an Amateur.*—Albert Smith used to tell us, in his memorable entertainment, that although no photographer himself, he had a friend who had considerably distinguished himself in the art. This gentleman had attempted a most difficult subject, and succeeded to his entire satisfaction, as Mr. Smith himself was ready to testify. The picture which the amateur photographer secured was one of Strasburg, taken from a distance and on a dark night, and, as the lecturer averred, the rendering was in every respect most truthful. Not a vestige of the town could be seen from the spot whence the result was secured, and similarly, nothing at all was visible upon the plate. This was probably the first well known joke made at the expense of amateur photographers, and in all probability, too, the last, for these gentlemen, instead of being behind their professional brethren in the art or science, are, as a rule, considerably in the van. At any rate, in England, we have learnt very much from the *dilettanti* section of photographers; and, to mention one instance more especially, the problem of dry plates has almost entirely been worked out, and the films brought to their present state of perfection, mainly through the efforts of gentlemen in this country who have spent much time and expense in carrying on investigations which were to them a pleasure rather than a duty. In other branches of photography the assistance of amateurs in perfecting our art science is also well known, and if so minded we could at once point to a score of clever and skilful gentlemen who have earned honourable mention as disciples of the camera. In France, in Switzerland, in Russia, in Germany, and other countries the work of amateurs has also stood prominently forward, and aided much in the progress of the art, and it will be a sad day indeed for us all when these cease to identify themselves with photographic art and science.

*How to render glass opaque or frosted.*—There is a capital plan mentioned in *Dingler's Journal* for frosting glass, or rendering it opaque, which may be useful to photographers, especially as it is one very easy to carry out. A sheet of ordinary glass, whether patent plate or crown does not matter, is cleaned, and if only portions of it are to be frosted, those are left bare, while the others are protected by mechanical means in any simple manner. Some fluor spar is rubbed to a fine powder and mixed with concentrated sulphuric acid, so as to make a thin paste, and this is then rubbed by means of a piece of lead upon those parts of the glass required to be rendered opaque. A fine frosted outline or design may thus be produced upon a sheet of smooth transparent glass. To finish the operation, the glass is gently heated in an iron vessel covered with a funnel passing up the chimney, to get rid of the noxious fumes that are given off; on cooling, the plate is washed with a dilute solution of soda or potash, to remove any acid yet remaining, and is then rinsed in water. Focussing glasses for the camera, and development glasses for pigment printing, can be prepared in this way at very little expense.

### AMERICAN CORRESPONDENCE.

THE PHOTOGRAPHER AND THE COLOURIST—HOW TO GROW AND IMPROVE.

*The Photographer and the Colourist.*—No doubt a great many prints are made by your leading photographers on unblanched paper for colouring upon; and no doubt your colourists grumble and growl over the prints they get as much as ours do. A word or two of friendly counsel, then, from a colourist to the photographer, for the benefit of both, which I quote from a letter sent me by one of the injured. After charging us to "be clean," and to carefully handle and mount the pictures, he says:—

"The tone, I am well aware, is a mooted question among artists, or so-called artists; for he who contends that the brown tone is the proper one does not fully understand his business, and I can prove it. There never can be made a clear flesh and blood face over a brown tone. Especially is it impossible to depict certain varieties of complexion true to life, with their marvellously pure sea-shell tints, and transparent blue traceries of veins. Where the deeper shadows are above the eyes, under the chin, and some other occasional shades, the tone does not matter—it is well enough there; but in the lighter shadows, on the temples, brow, under the eyes, about the mouth, and on the neck and bosom, there should not be a trace of brown; for these are delicate shades, greyish, or inclined to blue or green, and must be pure and transparent, showing no dirty under-current of any other colour, and especially any colour made in the photograph. The painting which shows the photograph peeping through its colours reminds one of that economical young woman who inquired how much it would cost to have one coat of paint on her picture. The photographic print should be used simply for the assistance its outlines give to the production of a correct likeness; that secured, it should be completely covered, painted out, and entirely lost for evermore to mortal vision—only the painting left, with its firm flesh and graceful draperies standing out independently from the distance of the background.

"Next come those artists who stipulate for a blue tone. That is not much better than brown, but is a little. I used to call loudly for that myself before I learned better. But there are certain complexions which cannot be painted any more successfully over a blue tone than can some others over the brown.

"Then comes that perfection of tone for all kinds and descriptions of to-be-painted pictures; the clear neutral grey, than which there can be none more suitable. Any photographer from whom I receive prints with this tone has my enduring respect. For crayons and inks this is the only one that is admissible, inasmuch as it is impossible to hide the photograph in those truly beautiful productions of art when the prints have any approach to colour, as red, brown, or blue.

"In the working of pictures which have a blue tone, a compromise is often effected by a mixture of colour with the ink, till the photograph's tone is, so to speak, infused into it. This, too, is done for working a brown tone, and the effect in the finished picture, although better than could have been gained without, looks like an expression of bad taste in the artist, when it is only his misfortune that he is compelled to resort to such means. The brown crayon print, though, is irremediable; for crayon cannot be modified by red or any other colour. Black they are as drifted charcoal, and black must they remain, though the print be as brown as a nut. And these pictures, bear in mind, are expected to delude people into the belief that they resemble fine lithographic engravings; and properly made they do, only that they surpass them.

"But do you not see that these coloured faces, stippled with black, bear not the slightest similitude to an engraving, with its pearly lights and effectively transparent shadows? To cover the brown tone of the shadows, the crayon must be ground in until it reaches a density that gives an effect too sooty for any white citizen. This never will do; so the brown shadows and red half-tones must be allowed to look through the crayon, the lighter parts of the background must remain of this same colour, so decidedly foreign and inimical to the supposed object of the picture, and the high-lights in the drapery must also take part in the general discolouration.

"Perhaps I have devoted too much time to this talk about tone; but I do not think that too great stress can be placed on its importance; for why should we not, in one piece of work as well as another, be fastidiously careful in every minor detail which goes to make up the grand result.

"When we attempt the portrayal of flesh in colours, on canvas or paper, all acknowledge that there cannot be too great care in searching out in the human face, and perpetuating in the pictured one, all the delicate tints and all the peculiarity and richness of colour that can be found, to make it approach, as nearly as lies in human power, the living, breathing original. Then why should not the photographer and artist work together to secure every means in their united power, to make ink and crayon pictures as minutely as possible like the engravings they represent?"

*How to Grow and Improve.*—We must all admit that in photographic portraiture, at least, great strides have been made during the past five years, and that there has been a wonderful awakening desire among the photographers for improvement. The source from which they may learn the

most is, of course, the magazines and books that are published especially for them, and it is cheering to know that many are willing to admit this, and show their appreciation of it by continuing to read. Mr. L. G. Bigelow, the author of the excellent "Album of Lighting and Posing" which bears his name, has recently been on a tour, and he sends me a few observations on this score which he made, and which I give you below, hoping they may show those who wish to grow and improve, and who don't know exactly how to go about it, the proper way:—

"After an extended tour in the west and northwest, I am able to say positively that the next exhibition of the National Photographic Association will be strongly represented by delegates and exhibitors from those sections. The desire to exhibit work seems stronger and more unanimous than on any previous year, and many at present unknown names will, after the Chicago Exhibition of 1874, stand in the front rank with our ablest professionals. Away in some secluded village, off from the main lines of travel, I have been startled with pleasure to find productions which will compare favourably with that produced in many metropolitan galleries. In one special instance, on inquiring as to the means used in acquiring the knowledge and taste exhibited in the work displayed, I found the photographer was a subscriber to twenty-five dollars worth of art literature per annum, among which was the *London Art Journal*, the *Philadelphia Photographer*, the *Aldine*, and *Mosaics*. From these, and starting with a natural taste for pictorial effects and a love for his business, he has risen to rank *par excellence*, as the next exhibition will probably prove. Everywhere I find the skilled ones the reading ones; and they show it not only in their work, but in their manners and conversation. They are wide awake to anything which will advance them in perfecting themselves in their business. Some are getting rich, and many of them are in prosperous circumstances. Most of them acknowledge that the way was shown them through the study of photographic publications, and above all by the meetings or reports of the National Photographic Association or its annual exhibitions. Most are already members, and nearly every one of those not joined expressed a determination to do so.

"Friends, there is another side to the picture taken on the same trip: men doing business so ignorant of their work as not to be able to keep out of the fog over half the time. Some do fair chemical work, but pose only to expose their ignorance of all art principles, and even of the mechanical laws of their business, and who do not know enough of their business to explain intelligibly to their customers the answers to questions every day asked. Such cases, of course, are rare, but they ought not to exist at all in a business which assumes and is generally recognized as a fine art. May the grand army of progress induce them to join its ranks, with the hope that, by example and precept, they may be led to become members in mind as well as name. The west is bound to make a grand showing at Chicago, and we say to all, 'look to your laurels.'" Truly yours,  
EDWARD L. WILSON.

#### IMPROVED METHOD OF MOUNTING STEREOGRAPHS.

BY PROFESSOR CHARLES F. HIMES, PH.D.

NOTHING is more annoying to any one who has, with great care and interest, made a collection of stereographs, than to witness their gradual, almost inevitable, deterioration by use, and often to be obliged to see defects that put in an appearance on the choicest pictures run their course without possibility of being checked until not only the beauty, but the value of the picture is impaired. No care in assorting, and arranging, and packing away in separate boxes, according to subjects, however it may reduce the handling required to find any picture that may be desired at any time, can prevent the wear and tear so injurious to this class of photographs. A book may have worn bindings, stained, and even partially effaced, leaves, but will only have its beauty impaired thereby, whilst its true, substantial value will remain. But long before a stereograph becomes unsightly to a casual inspection, or begins to show a loss in value, it may have lost some of that peculiar force and fulness with which it renders its account of any

subject in the stereoscope, under the combining and magnifying influence of the glasses of the instrument. This is not because the photograph is more tender or liable to injury, but because all points and specks of such pictures, however minute or apparently insignificant when viewed through the instrument, express much more than would be even suspected to be contained in a photograph. The dots may be removed from all the i's of a printed page, the letters may be defaced, words even half obliterated, and yet it may be completely read and understood; the deficiencies may be mentally supplied; but the stereograph owes its peculiar, almost magical power, to the unconscious, rapid combination of numberless apparently meaningless specks.

How many stereographs, on casual inspection without an instrument, present almost an appearance of meaningless, almost unsightly blotches of light and shade, and yet in the instrument acquire a force and beauty all their own. It is plain that any roughening or dimming of the surface of such a picture will rob it of more of its value than a similar treatment of one not to be subjected to such an examination; that there will be destruction of its wonderful wealth of details revealed by aid of the instrument.

But besides liability to mechanical injuries, the photograph is very sensitive to chemical influences; a creature of chemical reactions, a result of some of the most delicate and insensible operations of some of the most subtle of nature's agents, it seems to retain this sensitiveness to chemical influences, this subjection to agencies that do not in the least affect an engraving. No care in the preparation of it can relieve it from this liability to misfortunes peculiarly its own. Accidental touches with the fingers may, aided by atmospheric influences, originate a train of changes that will inevitably lead to the destruction of its beauty and effectiveness. As a partial preventive of the injury of the pictures from preceding causes, the revolving stereoscope certainly recomends itself; but it is expensive, cumbersome, and very limited in its capacity.

It seems strange, then, as the stereoscope seems now to have become something more than a novelty, and has its recognised place and value as a means of study and instruction, that something has not been done to remedy, if possible, the preceding evils, and at the same time render the pictures as easily consulted as books in a library. The old card stereograph holds its place just about as it came into the market with the first instruments. Attempted variations in size, even, have not forced their way into anything like general favour. And yet is there a form of photograph which wears a more unfinished, unattractive appearance than the stereograph, or is more unsatisfactory to handle? Now, at first, this form seemed most convenient with the form of closed box-stereoscope, introduced mainly through Sir David Brewster, into which the picture was slid. But with the almost endless variety of instruments now in the market, it would seem that a corresponding variety of modes of mounting the pictures might at least be attempted.

The writer, after suffering from all the inconveniences, especially for reference, entailed by the old and only form of mounting, during the growth of a collection of stereographs on various subjects for the past fifteen years, has adopted a plan which seems to relieve the pictures almost entirely from liability to injury from mechanical, chemical, or atmospheric causes, and yet permit of almost as ready reference to any particular picture as to the page of any book in a library, whilst the space occupied is, at the same time, much reduced.

A book is formed about three and three-eighths by three and a-quarter inches in size, with a dozen or more rather short guards, to which double leaves, the size of an ordinary stereograph card, are affixed, like maps in an atlas. Upon these leaves the stereoscopic pictures are pasted as on a card, and a slip of smooth, stiff paper laid on one, and the book closed and subjected to considerable

pressure—as of a copying-press—for a short time, or, still better, for several hours. Each book contains leaves enough for twelve pictures, and has a title-page and index-page in which the names and numbers of the pictures and of the negatives are placed, as well as of the series to which it belongs; as, for example, German series, vol. — No. —, &c. To examine such pictures the book is opened out and slid between the wire supports of an ordinary Holmes stereoscope, or into a box stereoscope with an opening at the top instead of on the side. The Holmes stereoscope is, however, preferable, and it is best not to open the book completely before inserting the edges in the wire supports, but to do so afterwards by gently pressing against the back of the book.

There are so few objections that suggest themselves to this mode of mounting stereographs, and so many advantages, that it might become an object with dealers to supply the general public with them mounted in this way, whilst for collections to be placed for public use—as books in a library—it seems specially adapted, since by suitable catalogues any desired one might readily be found and examined by a simple form of instrument placed near at hand. The range of subjects—scientific, architectural, mechanical, artistic, &c.—susceptible of illustration in this way would doubtless soon be added to. Instead of having such pictures already pasted in books, dealers might simply have them mounted on flexible cards, which could readily be folded and affixed to the guards of a proper book in a few minutes. Leaves of thin paper might also, if desirable, be affixed to extra guards, on which fuller descriptions, &c., could be written.—*Photographisches Archiv.*

#### M. CHARDON ON THE COLLODIO-BROMIDE PROCESS.\*

For some time past the preparation of dry plates has been studied on many hands. Every one has his own ideas on the matter, and numerous processes have been brought forward which are very similar to one another. The plan of preparing plates with bromide of silver in suspension in the collodion, a method known under the name of the collodio-bromide or emulsion process, differs from other systems, and, before giving it the preference, we shall do well to consider in what its real value lies. To do this, it is necessary to enquire into the nature of the qualities which dry plates should possess. Thus they ought to be:—

1. Easy of preparation.
2. Require but a brief exposure.
3. Possess good keeping qualities.
4. And develop within a reasonable time.

I shall not lay any stress upon the two first conditions named, but will say a few words on the subject of development. I believe, and this is but a personal opinion, that the image should not be very long in coming out, and by this I mean that the picture should present itself in all its details, whether it is of a weak or vigorous nature? If an acid solution is employed, the development will be rather longer than when an alkaline liquid is used; and here I beg to call attention to an important point, which is that developing and intensifying are often confounded. The development, as I have just said, should bring up the image in every detail, while the intensifier should only be resorted to to give the cliché a little better effect. It is by reason of this confusion that pictures of a hard character are so often obtained, the development not being complete before the operator has proceeded to intensify. I will add, moreover, that intensifying is by no means indispensable, and that a cliché which has never been submitted to the operation will be always much more harmonious, and yield a far more perfect print.

With alkaline development, which I habitually employ, I have no need to intensify my image, but in order to do

\* Read before the French Photographic Society.

this an excellent preparation is necessary, which is opaque, and which gives sufficient opacity to the image.

If now we examine the emulsion process, I find that in the preparation of plates it is superior to all others as regards the simplicity of the operations. As regards the exposure required, I do not share the opinion generally expressed that very short exposures are necessary. On the contrary, I have found that the period required is two or three times as long as that for plates sensitised in a bath. M. Stuart Wortley has obtained results in two or three seconds; but under what circumstances? It is only by forcing the development, and continually renewing the solutions; and then he obtains but weak images, which require as much time again to be spent in intensifying them as was previously necessary for their development. I have heard that the plates now purchasable in commerce under the name of Stuart Wortley plates possess good qualities, but those who have essayed to prepare them from the published formulæ have not succeeded. We must conclude, therefore, that the process has been brought forward more especially as a commercial speculation.

Coming back to my subject, I affirm that a lengthy development of this kind is not practicable, and that if it succeeds in certain hands it is, nevertheless, not within reach of all of us. M. Stillman, at the last meeting of the society, had the honour of submitting to your notice some clichés and a formula for preparing emulsions. I have prepared some plates with the collodion he placed at our disposal, and I regret to say that I have not been successful with it. I found in this preparation the defects which I have just indicated. May be, the collodion had undergone a change; may be, I have been unskilful; but, at any rate, I have failed to obtain anything. The collodion is extremely fragile, and, as you may see, the film could not be preserved intact. Wishing to make some comparative essays, I took two negatives with some plates that I had kept by me for a period of three months. These plates had been prepared by M. Stebbing, and they received an exposure three or four times less, and yet gave good clichés, without any intensifying at all. I do not wish it to be considered that I am praising M. Stebbing to the detriment of others, and I ought to say that I myself have never had an opportunity of preparing plates according to his formula.

#### THE TRANSFER OF VARNISHED NEGATIVE FILMS.

BY KOCH REICH.\*

For the purpose of peeling off the film from a varnished negative I prepare in the first place a mixture composed of the undermentioned material, viz.:-

Gelatine ... ..	60 parts
Acetic acid ... ..	90 "
Water ... ..	180 "
Ordinary soap ... ..	$\frac{1}{2}$ part

The above ingredients are mixed together, and then poured rapidly over the varnished film in such a way that every part of the surface is uniformly covered, and no portion treated a second time. The superfluous liquid is poured off and thrown away, for it cannot be employed again for the same purpose.

The film is then allowed to dry, and, when perfectly desiccated, some thick normal collodion is poured over it, to which a little castor oil has been added. This leather collodion, having dried uniformly over the negative film, will be found capable of being peeled off, bringing the collodion image with it.

Should the film, when separated from the glass, lack thickness, and it is desired to secure the cliché film of a stouter and more compact nature, the same may be treated with a solution of gelatine (without soap) after the leather collodion has been applied, and even with a second application of collodion if such is deemed necessary.

By employing this simple plan of proceeding, I may

mention that I have stripped upwards of a hundred negative films from glass, all of which had been previously varnished, without having had a single mishap. They were from plates prepared by the ordinary wet collodion process; but whether dry plates (and especially those which have been prepared with a substratum of albumen) could be so readily treated, is a matter of which I have no experience at present.

#### PHOTO-SPECTROSCOPIC RESEARCHES.

BY PROF. H. VOGEL.\*

A SHORT time back I gave an account of some photographic experiments I had made with the spectrum.† After I had succeeded, as there detailed, in discovering a method of rendering bromide of silver strongly sensitive to coloured rays, which, in its ordinary state, affected the salt but little, I tried other colouring matters and silver salts to ascertain their behaviour likewise under the influence of the spectrum.

These experiments were, it is true, performed at a very unfavourable period of the year; but they yielded a series of results which supplement very materially my earlier observations. In the first place, I found that pure bromide of silver was sensitive for all colours of the spectrum: for some, as a matter of course, more than others. The maximum sensitiveness lies between *h* and the point  $G\frac{2}{3}$  F, by which, according to Bunsen, I mean the spot two-thirds distant from the lines *G* and *F*, reckoning from *G* (see fig.). From there towards the red it gradually diminishes, and the diminution is more rapid towards the ultra-violet, the action being different at different times.

In the figure, line No. 1 shows an image upon pure bromide. In the sketch the spectrum lines are shown as perpendicular lines at the proper distances, and the wavy outline upon the horizontal line No. 1 indicates that the sensitive action in red begins at *B*, gradually increasing until it becomes most powerful in the indigo, and quickly diminishes in the violet. If there is the slightest trace of any light absorbing body mixed with the bromide of silver its action is at once apparent, showing at the point of the greatest absorption, also, a stronger photographic action, which is at times only observable in one line. Foreign matter of this kind is not unfrequently met with in commercial samples of collodion, serving as basis for the image. The spectroscope betrays the presence of these substances, the amount of which might be so small as to baffle chemical analysis.

I found, on further investigation, that with coloured bromide of silver the point of the greatest absorption of the colouring matter did not coincide accurately with the point of the strongest photographic action. I remarked, indeed, that the point where the strongest action took place was rather nearer the red than the absorption point of the colour. This circumstance cannot be wondered at, as the chemicals which come into play exert some influence, and the absorption power of the collodion film and bromide of silver also have their rôle to perform.

Of particular interest was the behaviour of chloride of silver. Pure chloride of silver plates compared with bromide of silver were found to be highly insensitive. Where bromide of silver gave a very vigorous representation of the spectrum from *H* to beyond *D* in fifteen minutes, chloride of silver yielded not the trace of an image with the same exposure. It was only after the exposure had been prolonged to thirty-eight and a-half minutes that I obtained any impression at all upon the chloride. This was most visible between *G* and *E*, left off in the middle between *g* and *h*, and continued gradually lessening to the other side into the red, so that line *B* was just slightly visible (see No. II line, in fig.) To judge from this one experiment, the sensitiveness of the pure dry bromide is much more comprehensive than that specified

\* Photographisches Archiv.

† Photographisches Mittheilungen.

† See PHOTOGRAPHIC NEWS for 12th December, 1873.

by Schultz-Sellac for moist chloride of silver. Schultz found only sensitiveness between the ultra-violet up to line H; but, according to the experiment just referred to, the sensitiveness extends through the whole spectrum.

Very remarkable is the behaviour of red chloride of silver. This showed itself to be the most sensitive in the yellow, a vigorous line being produced at D. The sensitiveness rapidly diminished both towards the violet end, where it extended to G, and the red end, where it ended at C (see No. III line in fig.) Thus, red tinted chloride of silver showed much greater sensitiveness than the pure chloride. Whilst the latter required an exposure of thirty-eight minutes to give a marked impression, the tinted compound gave a vigorous mark in the yellow within fifteen minutes. Chloride of silver tinted red would, according to this, be the ideal of photography. For ideal photography, which should reproduce reality—or, in other words, the tones in their comparative brightness should reproduce yellow as the lightest, then red and green, and then blue, which is to be classed with the darker colours. This is what the red tinted chloride does in fact, and if it were only more sensitive, it would be unquestionably the finest material for photography.

Red coralline bromide of silver is much more sensitive, but does not come so near to ideal photography, for it reproduces blue quite as brightly as yellow. I tried to employ a mixture of the two bodies. The red chlorobromide of silver gave a result half way between red chloride of silver and red bromide of silver. The compound showed itself to be most sensitive at D; from thence the action diminished very rapidly towards red, and ended 6 millimetres from D. Towards blue the diminution of sensitiveness was less rapid. Between F and G in the middle the sensitiveness again increased, and reached a second maximum near G, reaching to h, when it diminished rapidly, and disappeared 4 millimetres further on. (See No. IV line in fig.) The only gain, therefore, resulting from mixing the chlorine and bromine was an increased sensitiveness in the yellow, which, however, did not appear of sufficient importance to warrant the matter being carried further.

The examination of the iodide of silver furnished interesting results. Pure and dry iodide of silver showed a considerable sensitiveness for violet as far as green (H'—b.), then the action suddenly ceased, but could be traced in the red for two millimetres beyond B. Here also there was a much more widespread sensitiveness indicated than experiments hitherto made had shown. Bromo-iodide of silver behaved in a peculiar manner. An ordinary wet plate showed on the 29th October, with an exposure of ten minutes, at 3 h. 6 m. p.m., a very vigorous action at G, for here a most marked line was produced; the action remained pretty uniform until line E, and was lost in the middle between D and E. Towards violet the action only went two millimetres beyond H (see No. V line). A much more notable action was obtained on the 7th November, when the sensitiveness extended into line

D, and on the other side until 7 millimetres beyond H. I make this remark only to prove that on different days the action of the light is different. In general the action is the most vigorous between h and F, and the maximum action lies 2 millimetres from G towards F, when the elevation in line V (see fig) is shown. By reason of this difference in the action, it is necessary that the comparative results be made at one and the same time.

Washed wet plates behaved quite differently to the bromo-iodide of silver plates with nitrate of silver; the strong line at G was no more to be seen, but instead, there appeared on development a brown band about G, which in different experiments appeared of unequal intensity and breadth, and very near appeared the other part of the picture in pure blue. On the 30th October, 1873, I obtained a picture which began in E, was most vigorous at F, and diminished towards G, and disappeared before H (see line No. VI). On the 1st November the action extended into the yellow, and on the other side to H, and was more vigorous at G, as the dotted line shows.

These experiments show the great influence of the sensitizers upon the film.

A washed and dried collodion plate behaved again differently, for its sensitiveness first began in the violet at h, (13 m. from G) then diminished until 2 m. beyond G; then began a very vigorous action, which reached nearly as far as c (1 m. from E). Immediately beyond E the action disappeared (see line VII in fig.)

A tannin plate of the same kind of collodion was then tried. In this a vigorous action from H' to 2 m. beyond G was shown. Then it became suddenly weaker, and lasted till near E. At E the action was a little stronger, although still very slight, and it disappeared near D. Other tannin plates gave a similar result, only the action went more or less in the direction of the violet, or the red, according to the intensity of the violet and red rays.

Singular was the behaviour of red tinted bromo-iodized collodion. As a dry plate it gave a result such as shown at line VIII. The strongest action was at G, then it suddenly diminished, and again became more marked near F. Exposed wet with nitrate solution, the result was totally different (see line IX). In this case the greatest amount of sensitiveness was in the light blue at F, and diminished towards the dark blue and violet, appearing again vigorously near G. This red bromo-iodide of silver, when moist with nitrate solution, is more sensitive, therefore, to the less, than to the more, refrangible rays. As may have been seen in the illustration, however, in no case with portrait collodion was there any sensitiveness in the yellow and red. It is obvious that the colouring matters added to collodion would soon get into the nitrate bath, and the latter would soon show the effects of organic contamination.

The following conclusions may be drawn from these experiments:—

1. Bromide, chloride, and iodide of silver are sensitive to all the colours of the visible spectrum, but least so in the ultra-red rays.
2. Chloride of silver coloured with coralline shows most sensitiveness in the yellow.
3. Coloured bromo-chloride of silver shows a sensitiveness midway between that of its coloured component parts.
4. Bromo-iodide of silver with nitrate solution (the ordinary wet plate) is most sensitive at line G (dark blue). The sensitiveness diminishes slowly to green, and quickly to red.
5. Washed wet and dry bromo-iodide of silver shows itself very sensitive for light blue, and less sensitive for dark blue and violet.
6. Dry red bromo-iodide of silver is more sensitive for dark blue than for light blue.
7. Red bromo-iodide of silver with nitrate of silver solution shows most sensitiveness in green and light blue, less sensitiveness for dark blue, and least for violet.
8. Tannin preservative increases the sensitiveness of bromo-iodide of silver for violet, but not for blue.

### ELIMINATING HYPOSULPHITE FROM PRINTS.

We have been favoured by Dr. Anthony with some interesting illustrations of the results obtained by the use of acetate of lead for eliminating the final traces of hyposulphite from the silver print. The method in question has been referred to of late, for distinction, as Mr. Newton's method, that gentleman having revived the plan about a couple of years ago, and brought it prominently under the attention of American photographers. Dr. Anthony's experiments with the lead salt belong to a pre-collodion period of photographic history. The use of acetate of lead, and other salts having a similar reaction upon hyposulphites, has been, as old photographers know, often suggested, and occasionally tried, the aim generally being to oxidize the traces of the unstable hyposulphites of soda and silver lurking in the prints, and convert them into harmless sulphates or acetates. Besides the lead salts, various other agents have been suggested and tried. Dr. Angus Smith suggested peroxide of hydrogen, Mr. Hart suggested hypochlorate of soda, Mr. R. D. C. Tiehborne proposed chlorate of barium, Dr. Vogel proposed iodine. From a variety of causes, none of these have come into general use. Their use seemed to involve a certain trouble, and an uncertain advantage. In very few instances, indeed, have any of the methods received systematic trial with a view to compare their results with those produced by simple washing after the lapse of a few years. The committee formed in New York for that purpose reported, as we announced last week, unfavourably. Dr. Anthony's experiments are very interesting, inasmuch as they possess the especial value which lapse of time can give as a full means of testing. The prints he forwards for our inspection are certainly not faded, so far as that term implies partial effacement of the image, but they are slightly tinged with the sulphur hue in the whites. The plain paper prints are less changed than those on albumenized paper, giving further colour to the suspicion that the albumen is answerable for much of the instability of prints on albumenized paper. The plain paper prints are of a purple-black tint, and do not appear to have lost anything of their pristine vigour during the quarter of a century which has elapsed since their production. The albumenized prints are of a somewhat peculiar tint, approximating to mauve, the whites of a pale primrose tint. How much change they have undergone we cannot say. On the whole, the influence of the acetate of lead does not appear to have been injurious, but probably useful in Dr. Anthony's hands. Of the two other individual experimentalists who have recorded results, both have been favourable. Dr. Maidstone Smith, last year, gave us de-

tails of some trials made upwards of a twelvemonth previous, which were favourable to the lead salt, and Mr. Gregson stated last year a similar experience. On the other hand, a committee appointed by a society to test carefully, find that the prints so treated really change more than prints produced under similar conditions washed in the ordinary manner. The difference in experiences is probably to be accounted for by some difference in treating the prints after the application of the solution of lead salt. In the reaction which follows the immersion of the partially washed prints in the acetate of lead solution, sulphate of lead and acetate of soda are formed; and it is important that a very thorough rinsing should follow, for if any trace of the sulphate of lead be left in the texture of the paper it would certainly turn yellow by contact with the traces of sulphuretted hydrogen generally present in greater or less proportion in the atmosphere of large towns. Hence, unless care were used in washing the prints after the eliminating process, the very operation intended to remove unstable and deleterious hyposulphites might introduce another element scarcely less deleterious. Dr. Phipson suggested the introduction of one per cent. of nitric acid into the washing water after the eliminating treatment, to remove the risk it involved, and in further experiments this precaution may be worth trying. In the meantime we think that more reliance is to be placed on thorough and short washing, employing some mechanical aid to the removal of the hyposulphite, such as sponging or pressure, than upon methods of decomposing the final traces of the fixing bath, which may cling to the prints after inefficient washing.

### WATER IN COLLODION.

THE addition of water to a horny, repellent collodion has been practised for years with advantage; and, as we pointed out last summer, the free use of water in collodion, for subjects requiring long exposure in hot weather, is the best means of avoiding stains from the drying of the film. In the course of a discussion at a recent meeting of the Photographic Section of the American Institute, the addition of water to collodion was recommended as a means of obtaining increased sensitiveness. Mr. Gardner, referring to the subject, said:—

"I believe it is a mistaken idea to avoid the entire use of water in collodion. I had taken the greatest pains to get the best alcohol to make my collodion, but found it was not working very well, when an operator, looking at one of the negatives, suggested that I should add some water to the collodion. I added the water, so that it threw down a small quantity of the cotton, which redissolved again; then I tried it, and found it to work very satisfactorily. Since that time I have believed that a small quantity of water is not objectionable in collodion. When I used the iodide of ammonia and the bromide of ammonia instead of using alcohol, I dissolved them in water and passed them through an ordinary filter into the collodion. I have never found any mode of making collodion so quickly as by preparing it simply with water." Another member, Mr. Mason, said: "Twenty years ago we used to be very careful about getting water into the collodion. Two years ago, when a discussion came up here, I remarked that I had tried the experiment of adding to twenty ounces of collodion four ounces of water. The collodion was made with ninety-five per cent. alcohol and ether equal parts. I dissolved my salts in water, using potassium principally, and continued to add water until I had added four ounces." Further testimony was given by Mr. Chapman, who said: "I had some collodion, a short time ago, which was very rigid and worked very slowly. I thought I would add a little water to see if I could not make it a little tender. I did so; and it improved the sensitiveness nearly a third. It seemed to be as open and porous as the best collodion I had, while the cotton was absolutely good for nothing for my work without the water. When collodion is tough, I think by adding a little water to it, it may be improved very much."

In adding water, it must be done with great care; we have found a couple of drops in an ounce of collodion make a great improvement. It should be added a drop or two at

a time, shaking the collodion meanwhile. It is better to add too little and try, than to add too much, as that is difficult to remedy. The effect of too much is to make the collodion glutinous, yielding an uneven and crapy film. It is a good plan to experiment upon part of a stock of collodion, so that if by chance too much water is added, the fault may be remedied by adding more collodion.

#### A FEW BACKGROUND HINTS.

WE cull, for the benefit of our readers, a few hints on backgrounds which have recently appeared in various pages. They are not strictly new, but they all possess some points of novelty to be of possible service to some portraitists. The first is contributed to our YEAR-BOOK by Mr. A. Asher, of Edinburgh; and we reproduce it here for the special purpose of illustrating it by an engraving which was not ready in time for the pages when we first issued it. Mr. Asher describes it as valuable in all kinds of portraiture, but especially useful for pictures in which effective light and shade are employed to produce the results which photographers term "Rembrandts." Here is the figure.

Mr. Asher's description is as follows:—

"The framework, of wood, is circular-shaped, arched across the front, and dome-shaped from front to back of top circle. The dimensions for bust or three-quarter portraits may be about six feet wide in front, two feet deep in middle of circles; height four and a-half feet at sides, and six and a-half feet at top of arch in front. Any joiner can easily design and make the framework. Thin laths similar to those used in Venetian blinds, and which are easily bent to the dome shape, are nailed close together on to the framework, any inequalities being easily pared away. When the laths are all fitted and nailed down, give them a coat of strong glue size, which allow to dry; then cover over with cotton cloth, not too thick, using strong flour paste both on the cloth and over the laths. Lay on the cloth as smoothly as possible, taking care not to let the edges of the cloth lie upon the joinings of the laths. When dry, give a coat of oil paint, any suitable colour (the paint assists greatly in binding the cloth and wood well together). When the paint is dry it may be size-coloured to any shade desired. If one coat of size

does not cover solid, give another, having as much glue size in it that it will not rub off with the finger when dry. A few large castors screwed to the bottom of framework render it very portable, a touch bringing it into any desired position. The trouble or expense of producing this 'miche' background will never be regretted by any one adding it to his accessories."

In the *Photographer's Friend* (published in Baltimore) we find a somewhat similar background, with an addition of side screens and reflectors. Here is the figure.

The inventor, Mr. F. Waller, gives the following hints for making such a background:—

"In the first place there is a circular platform of five feet diameter and ten inches high, neatly carpeted, on large rollers, and provided with handles for running it about. The background frame is seven feet high, and is exactly half of a circle five feet in diameter, so as to fit closely around the platform. It has three rollers, one at the centre and one on each side. It is not attached to the platform, because it allows of greater freedom detached, though they will both move easily together. At each side of the frame is a hinged skeleton door, in which is an upper and lower swinging screen controlled by thumb-screws. These doors are two feet wide, and extend from the top of framework to the top of platform, clearing it so as to swing in or out. The woollen background—cloth is used, of light colour—in stretching it draw only from the top and bottom, when it will take the form without wrinkles. It should be rendered opaque by being covered on the back with dark muslin. The side screens are covered with white muslin only. The side screens may be used as light screens, to cut off or soften the light, or as reflectors to the shadow side. By the double arrangement the full flood of light may be directed upon the face, and the lower part screened. This is a great advantage for light draperies; for very black draperies they may be reversed."

In the *Philadelphia Photographer*, L. M. Whitney describes his mode of making a circular background, which, he says, is light, cheap, and useful. He writes as follows:—

"Take two pieces of bent felloes for the hind wheel of a buggy; spring them out so that they will span about five feet; ten on the ends for the corner posts; let the posts run past one inch; frame strips in between once in six or eight inches; take the heavy brown paper for sheeting up buildings; tack on inside two thicknesses, breaking joints; now take thin brown paper, and glue strips over the last joints; mount on four table castors; paint one coat of lead or brown, and it is ready for use. Cost, one half day's work, and \$2 for stock. Is very light, and easy to handle."

In the same excellent journal Mr. T. C. Harris describes another background of the same character, also easy to make at home. It is as follows:—

"A good cheap background for 'Rembrandt' heads can be made by gluing together three or four layers of paste-

board, so as to make a large heavy card about five feet square. This is to be cut into a perfect circle five feet in diameter. Over one or both sides of this paste one thickness of common muslin; when dry, cut out of this circle a triangular piece with the point of the triangle exactly in the centre of the card. The base of this triangle will be at the edge of the circle, and the width will govern the concavity of the background when finished. Now bring the edges of the cut together, giving sufficient lap, and rivet firmly with ordinary copper rivets placed about two or three inches apart; around the edge of the whole tack a wooden hoop to give stiffness. Afterwards paint the desired shade on the inside, and mount on a light wooden frame or an old head-rest. This makes a very good substitute for the ready-made grounds, and is especially recommended to those whose supply of 'stamps' is not sufficient to buy one."

#### ACETATE OF LEAD FOR REMOVING HYPOSULPHITE FROM PRINTS.

BY JOHN ANTHONY, M.D.

As a supplement to the interesting experiments lately made in New York on the effect of soaking prints in a solution of acetate of lead subsequent to their treatment with hyposulphite of soda, I am fortunately enabled to supply some valuable evidence of the effect of time—about a quarter of a century—on prints so treated with the lead salt. The specimens I sent to our worthy editor for his criticism were taken and printed from some two or three years before the invention of collodion, which, of course, fixes the date sufficiently near. Negatives at that time were necessarily taken on paper, and occasionally the paper negative was well waxed to make it transparent, and to as far as possible get rid of the texture of the paper, which was apt to appear in the print. I send negatives of each kind, and prints taken from them at the early period of the art I mention. Some of the prints are on plain paper, and some on paper slightly albumenized. It was usual in that day to print on plain salted paper by the process known as of Blanquart Evrard, that is, by ammonio-nitrate of silver; and the toning was invariably done by old hyposulphite solution—the richer in silver the better. It will be seen that the two prints so printed and toned have kept very well, and only one print shows three spots of the characteristic deterioration. One print on plain paper of the same subject, and from the same negative—the Egyptian head—was soaked in a solution of acetate of lead after it came out of the hypo. It will be known by its appearing rather purple than brown. For a long time these lead-treated pictures retained the tone they gained in the lead solution, viz., a delicate lilac; but the shade seems to have changed by time, and in the prints on albumenized paper which accompany their respective negatives the colour has merged to a pinky lilac—not an unpleasant tint. There is rather a yellowing of the whites from age, but, as will be seen from comparison with the negatives, no great amount of general fading. So far as I remember, it was imperative to print these specimens, which were intended to be "leaded," deeper than the others, as the acetate solution appeared to reduce considerably.

I must say that the prints did not behave as I expected. I was prepared to find them darken under the influence of sulphur and lead, but, as will be observed, they were rather bleached. Heaven knows what the chemical change was. The treatment was terribly empirical, and we were not in that day very particular about the strength of our solutions; but one thing we did very conscientiously, and that was, to wash the prints very thoroughly, whether taken at once from the "best hypo," or treated subsequently with this said solution of acetate of lead; and perhaps this may account for (I think I may say) the good condition in which these early photographs appear, with no special care used in their conservation.

I have no time to experiment further in this direction,

but I shall be happy to answer any questions on the matter, and to show the time-honoured specimens which remain to me fully illustrative of the point at issue.

Washwood Heath.

#### DESCRIPTION OF A PHOTOGRAPHIC STUDIO.

BY SAMUEL FRY.\*

I HAVE with much pleasure consented to the wish of your worthy secretary that I should read a paper before you.

For some years the South London Photographic Society has, in a very praiseworthy manner, made the furtherance of the art qualities of photography its leading feature, and none can do otherwise than admit that this has been of very great advantage to the commonwealth of photography.

Early in last year I built the studio of which a model is now before you. For the previous ten years I had satisfactorily worked in one; but at that period, owing to the unexpected erection of a large building immediately adjoining, my light was so completely taken away that I had no option but to build another. Fortunately, the extent of the land on which the house stands enabled me to do this.

The change in public opinion of photography, showing an immediate appreciation of art qualities, and subtle effects of lighting, determined me to erect a building capable of giving a great variety of light with promptitude in the changes. You will remark that the side-light is low—six feet only—and prominence is given to a large roof light, combining the united influences of side and top-light, of which the proportions may be indefinitely varied according to the form of the sitter's visage. Either end is available, and a very slight change in the blinds only is necessary to secure the full results.

The aspect is north, slightly inclining to east. During the summer months the early sun, up to about half-past nine, shines in, and it is then clear for the rest of the day. The height of the roof was designed from careful calculation so as to just exclude the midday sun on the longest day, and the result has been exactly achieved. Had the roof been any lower it would have required an external blind running along the ridge to do it.

On the side lights I use no blind, employing instead large, light folding-screens, covered with dark material, and having the outer leaf or fold of the screen covered with transparent muslin; by manipulating this screen between the sitter and the light a great variety of effects are very readily obtained. Nothing of this kind is obtainable with blinds, unless in very peculiar aspects.

I now ask your attention to the square window in the north wall. This is of ground glass, was especially made to produce Rembrandt effects, and is very successful. This is a model of the large screen at the end of room, which covers up the window when not in use. One side of the screen is covered with a lightish-brown cloth, in one piece, and the other side with a French grey. This latter is used for vignettes. By the way, I may here remark how very often we find vignettes taken on a dark background. Nothing can be worse, leading to dark patches over the head and shoulders, and the delicate outline of the hair is lost or becomes indistinct. The beautiful vignettes of the late Mr. F. R. Williams, and those of Mr. Reutlinger, were taken on lightish-grey screens.

When we wish to take a Rembrandt picture the screen is turned at an acute angle to this window, with the lighter side inwards, thus tending to mellow, by a gentle reflection, the tendency to extremes of lighting. By this system the camera is placed in or near the middle of the room, and the screen is so made as to cut off the light from the window from the lens. A large variety of effects are here produced, and a reflection of grey paper is often wanted to prevent masses of extreme shadow on the off side. Pictures produced at this window are the favourites with the public;

\* Read before the South London Photographic Society.

the choice of the usual set of four poses being generally for the largest number from this negative. Necessarily a prolonged exposure is required, which is still further increased if dark dresses are worn. This, however, you cannot help.

For another class of pictures, of which an example is before you, having a considerable proportion of the face in soft shadow, but with less vivid or decided effect than is produced at this window, I place the sitter near the middle of the room, and with one of the large screens drawn pretty closely up, I manipulate until this effect is seen. The camera is at a rather acute angle to the light, and will, therefore, need to be carefully shielded to prevent fog. This system does not require an appreciably longer exposure than with ordinary lighting. For ventilating there are two louvers, each two feet square, movable by a cord from within. They, without admitting light, speedily cool the upper part of the studio in summer, and, as the side lights lift completely away, the interior is kept very cool, entirely free from the close and noxious feeling of closeness so common in studios. For warming in winter, pipes pass round the studio, near the floor, and through the other rooms used for business; also through a cupboard, which forms a hot room for warming baths and solutions, drying plates, &c. Thus the extremes of temperature, so trying to photographic operations, are, as much as may be, neutralised, and this seems to complete the set arrangements devised for this studio. Equally complete, with as many novelties, and as successful in working, are the arrangements for enlargements and also for printing.

#### REMARKS ON THE ENLARGEMENT OF NEGATIVES BY THE WET PROCESS.

BY J. POLLITT.\*

It is with considerable diffidence that I appear before you to-night on the subject of enlarged negatives, following so closely on the heels of Mr. Brier, whose able and well-delivered remarks interested us all so greatly at the last monthly meeting. True, I had intended at some future meeting to bring before you some results of my own attempt at enlarging, but had not the slightest idea of doing so on this particular occasion until within the last few days. It was then made known to me that Mr. Coventry would, in consequence of absence from home, be unable to fulfil his promise of a paper for to-night, and that, therefore, the gap thus created should in some sort be filled up.

The principle of making small negatives, and afterwards reproducing them on a greatly enlarged scale, is one which promises so immensely to lessen alike the toil of the amateur and professional during a summer campaign, that it is not to be wondered at that so much should have been said and written in its favour, and so many experimentalists should have devoted their attention to its more complete development. But the idea of going out with a small satchel camera and plates of 4 by 3, or thereabout, and, by a second operation conducted quietly at home, enlarging them to the extent of four diameters, instead of the heavy 12 by 10 or 15 by 12 apparatus, and its concomitant weight of glass plates, is in itself so fascinating that, supposing the results thus obtained should fall somewhat short of the intrinsic excellence of a large direct negative of the highest quality, taken with a lens of long focus, there is a temptation to look upon it with some degree of favour.

I am, however, inclined to think that it is at present an open question whether, by having a small negative of sufficient merit, an enlarged one made therefrom may not, in some respects, be better, and optically more perfect, than a large direct negative, taken with a lens of great focal length; for it is well known that when a lens of short focus is used, all objects beyond a certain distance from the camera—that distance being determined by the focal length

of the lens—are, for all practical purposes, equally sharp in focus. You will doubtless perceive this in many of the examples I have with me to-night, being enlarged from negatives made with small lenses; whereas with a lens of long focus it would be absolutely impossible to get objects in so many different planes of distance of equal sharpness with these examples. Generally, the only approach that can be made thereto is by the trick of swinging the plate either vertically or horizontally, and sometimes both.

Thus, the optical conditions being theoretically more favourable to the enlargement method, it remains to be seen whether skilful manipulation can bring about a successful issue. Of course there still remains the difficulty of roundness of field, which is more or less the weak point of all lenses. You will, no doubt, detect some such remissness of marginal definition in some of these examples; because when such failing exists in the small negative the evil is, of course, greatly intensified in the subsequent enlargement. I do not know whether it will ever come within the scope of optical science entirely to overcome the difficulty; but in the best made objectives the evil has been reduced to such a degree of insignificance that, when all needful precautions are taken, it ceases to become a very serious objection, and where everything else is so good I should not be disposed to find fault.

Whilst some differences of opinion exist as to the best process for the production of high-class enlargements, the importance of working from a transparency of unblemished excellence is universally admitted; but of the many methods by which that transparency may be made, only two may be fairly said to lay within the scope of the members of this society, viz, the printing of the transparency by the superposition on a dry film of the original negative, or the printing from that negative by means of lens and camera on a wet collodion film. The former of these methods was ably dealt with by Mr. Brier at the last monthly meeting, and the excellent examples he brought forward on that occasion are quite capable of holding their own when brought into competition with anything I shall be able to show you to-night. It is, therefore, from no captious spirit of rivalry that I appear before you as an advocate of the wet process, but rather to help on the already mooted inquiry as to the best process.

If the nature of the transparency is of paramount importance, so also the nature of the small negative is not a whit less important; for it is here where the utmost skill and most artistic judgment are demanded. It is not sufficient that it be of average excellence, but it should be of marvellous perfection, and as microscopically sharp as it is possible to get with the best lens up to the very corners of the plate. It should be photographically thin, *i.e.*, too thin for good paper printing, well exposed, and full of detail; for in an under-exposed plate, forced up by prolonged development, the film presents a coarse, granular effect under the microscope, which, however well it may answer for paper printing, will never make a respectable enlargement. I also prefer the negative unvarnished.

Several of the examples I have brought with me to-night are produced from Professor Piazzi Smyth's beautiful negatives of the Great Pyramid, taken in 1865, and kindly lent to me by him for the purpose of making myself a set of lantern pictures from them, and also with the further privilege of publishing such copies at discretion.

These negatives were taken with the greatest skill and care, chiefly for the purpose of printing transparencies for the lantern, the camera in every instance being carefully levelled with a spirit level, and tilting being always scrupulously avoided, thus securing the more perfect freedom from distortion. Their general excellence is such that, I venture to say, they will not suffer by comparison with the very best works of the best living photographers. I have brought with me some of the transparencies from which the enlargements have been made. I cannot let you see the negatives themselves, even were I at liberty to do so, for they have

\* A communication to the Manchester Photographic Society.

never been varnished, and therefore would not be safe to handle; besides, I promised that they should suffer no deterioration in my hands, nor, in fact, be subjected to any risk; and that promise must be religiously kept. The average amount of amplification to which the pictures have been carried is about three and a-half diameters of the originals, some of them being a little over four diameters.

I may here remark that, although a negative may sometimes be amplified to the extent of six diameters with perhaps increased artistic effect, I do not think it advisable as a rule to increase to more than four diameters. The half of a stereoscopic negative will on this scale produce a good 12 by 10, and I think then our ambition ought to be satisfied.

The success of the wet collodion process for making the transparency depends largely on the use of gelatine in the iron developer, while it depends in part on the use of a collodion well ripened with age, somewhat thin, and not too rich in the bromo-iodide salts. I need say no more about the collodion, except that if, when the film is excited in the bath, it presents a dense and creamy appearance, it should be diluted with plain collodion and ether.

The gelatine solution used in developing is made by an old and almost forgotten method given many years ago by Mr. M. Carey Lea. I can give you the formula, although I have never actually made it myself; and for the stock I am now using I am indebted to Mr. Sidebotham, who gave me a bottleful about two years ago. As it had then been made some years previously, it was reported to be a fine old crusted sample. Whether or not age really confers on it some improving qualities I am not in a position to say. The method of making the solution, as given by Mr. Carey Lea, is as follows:—Add an ounce of sulphuric acid to three ounces of water, and set aside to cool. Then add to this liquid an ounce of good gelatine; let it swell and dissolve, placing it for that purpose in a gently-warm place, not exceeding blood heat, for twenty-four hours. Then add iron filings in excess, avoiding all application of heat; let it stand for several days. Finally, add a little acetate of soda, filter, and dilute to fifteen ounces. I believe it will be found necessary to dilute before filtration.

The above formula was given at the time as a new developer to be used alone, and I remember trying it in 1865 in conjunction with the late Mr. Petschler; but it did not then answer in our hands used alone, the development being exceedingly slow, and the films had, on drying, a most tantalizing habit of splitting into ribbons and curling up after the fashion of wood shavings, leaving the plate quite bare. The best results I have obtained in transparencies have been by a very sparing admixture of it with an ordinary iron developer of about twelve or fifteen grains to the ounce, using the gelatine solution in the proportion of about one drachm to two ounces of the iron developer; and such has been the plan adopted in making the transparencies from which these enlargements are produced.

I need hardly point out that the conditions demanded in such transparencies are, that the exposure shall be more ample, and the development carried on further, than is necessary in the production of lantern pictures. I have only brought with me a few of the transparencies; these will be sufficient to show the conditions desired in every case. I deprecate the use of varnish except on the enlarged negative for printing. The best transparency will be produced from a thin unvarnished negative, and such transparency in its turn (still unvarnished) will produce the best enlargement.

I have here a picture enlarged from a negative by Mr. Lund, and, I dare say, well known to many present, because it has been shown on the screen and recognized as a high-class lantern picture. It is from a varnished negative which has been used for paper printing, and, as a consequence, I do not think the effect is so good as the productions from the unvarnished ones, although the negative in itself is of equal excellence.

The safety of an unvarnished negative would, of course, be seriously endangered by contact printing, and besides this drawback, unless the best patent plate be used both for the negative and transparency, there are many chances against getting an absolutely sharp print; but, supposing every precaution to be taken in this respect, immunity from risk is not then always secured. Minute excrescences on the varnish will sometimes attach so firmly to the film of a dry plate, when brought in contact with the negative, that a separation cannot be made without utter ruin to it.

I think I have now sufficiently stated my case in favour of the wet collodion process as a means of producing enlargements, and I shall not trespass farther on your time than is really necessary.

I now come to the manipulation of the enlarged negative, and this is simply a repetition of the method used in making the transparency, with one or two slight modifications. I use a somewhat heavier collodion, also a stronger solution—say twenty grains to the ounce of iron solution—and half the modicum of gelatine solution. I also intensify with pyrogallic acid, acetic or citric acid, or both mixed, and silver after the ordinary fashion before fixing. I prefer, however, not to carry it quite up to printing density, but after fixing with cyanide of potassium to intensify just a little further with the pyrogallic acid and silver solution. This application, when judiciously performed, strengthens up the highest lights, and gives sufficient crispness to take away the flatness which might otherwise stigmatize the negative as a copy.

On the camera and lens arrangement I need not dwell, Mr. Brier having so clearly described it, and the arrangement itself being so exceedingly simple as to suggest itself to the most ordinary mind.

Of the various lenses spoken of, my own preference is decidedly in favour of the rectilinear of Dallmeyer, or the doublet of Ross, either rapid or wide-angle, for I have tried them both without satisfying myself as to which is the best; but in either case the best results will be obtained by using a lens which will cover well a larger plate than that from which the enlargement is made.

I have now endeavoured to give, with all the particularity that the limited time at my disposal has allowed me, an account of this method of enlarging. I had hoped, before preparing such a paper, to have done more actual work; so far as I have gone, however, the results are before you, and will, no doubt, be estimated according to their proper merits.

#### PRECIPITATING SILVER FROM WASTES.

BY J. CHISHOLM.

It is a common practice with photographers to throw down their silver as a chloride. I prefer commercial hydrochloric acid in all cases in all solutions containing silver. I take hyposulphite solution of silver, for instance; I put hydrochloric acid in the solution, and it sets the sulphur free in half a minute. Pour in enough—it is cheap—and, as soon as the sulphur is set free, the chlorine acts upon the silver, and precipitates it as a chloride. The sulphur is set free as a yellow scum, which goes down by its own gravity. When the chloride of silver is formed, it falls to the bottom of the vessel at once with the sulphur. When that is done, stir it up thoroughly, and then decant the supernatant liquid. Then add commercial nitric acid with hydrochloric acid—it does not matter much what is the proportion—and the two acids combined will act very energetically upon the sulphur, which will rise and float upon the surface; then you can separate it from the chloride, and wash it as many times as may be necessary.

*Precipitation by Copper.*—Another process is to get pure metallic copper. I take a sheet of copper of a size the dish will hold, and clean it on both sides. I suspend that in the hyposulphite, and there is a galvanic action set up, which takes all the silver out of the solution, precipitation commencing on both sides of the copper as metallic silver.

When it is sufficiently accumulated there, it is likely to fall to the bottom of the vessel by its own weight. When it does not do that you can take a common spatula and clean it off. You can keep copper there all the time, and the process will continue all night, while you are asleep; you can take some of it out to find whether it is all down or not. Take a little in a test-tube and try hydrochloric acid with it, as before, and if there is silver in solution the chlorine will go to it, and you cannot separate them without re-dissolving with ammonia.

*Reducing Paper Waste.*—I make a strong nitrate of potash solution, then soak the paper in that thoroughly, let it drain and dry thoroughly, put in another batch, and dry it in the same way. When they are all perfectly dry, I burn it in a shovel, and the silver will be in the ashes. If you do not use the potash solution there will be a great deal of organic matter, and it will be difficult to get rid of it. If you attempt to burn the paper without it upon a shovel, there will not be draught enough to burn it thoroughly, and you cannot put it in a draught, because you will lose too much.

## Proceedings of Societies.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held on the evening of Thursday, March 12th, the Rev. F. F. STATHAM, M.A., in the chair. The minutes having been read and confirmed.

Mr. SAMUEL FRY read a paper on "Glass Houses" (see p. 144) The subject was admirably illustrated by the aid of a wooden model, and small screens and backgrounds, which were placed in their various positions, as illustrating their uses in securing different effects. Some fine examples of the various styles, produced by different modes of arranging the screens and blinds, were also shown.

After a few words from the Chairman on the interest and usefulness of the paper, and a vote of thanks to Mr. Fry,

Mr. BLANCHARD said he thought Mr. Fry had gone on the right tack, to secure both rapidity of exposure and good results, in bringing the eaves to the side light, at a height of six feet, and securing a very acute angle for the roof. In that respect it was like one of the best studios he knew—that of Mr. Robinson—and it also resembled that of Mr. Hughes. In the studio of Mr. Robinson, as in that before them, the direct sunlight of summer middays was cut off by the acuteness of the roof angle. In Mr. Hughes's it was cut off by another narrower studio being built above it. The result of having such a studio was, that during three-quarters of the year it was scarcely necessary to touch a blind. He thought another improvement would be, to have a portion of the roof sliding off altogether, so as to admit light without glass at all. Glass in London was practically a semi-opaque medium, and its removal would shorten exposure one-third.

Mr. W. F. MORGAN had adopted that plan in his studio, and found it a great advantage.

Mr. BLANCHARD asked what was the average exposure in Mr. Fry's studio, say with a Dallmeyer's 2b, full aperture.

Mr. FRY said, take the average the year round, about ten seconds or less. In answer to another question, he said his studio was twenty-two feet long by fourteen feet wide.

Mr. HUGHES, in answer to a question, said he originally put Hartley's rough green glass in the roof, with a view to subdue to the top light. This was found in winter to interfere with rapid working, and was removed, and its place supplied with large sheets of patent plate. This effected a great improvement for winter working at first, but eventually, an accident having shown that this patent plate had become much yellower by exposure, they again returned to the rolled green glass, in which, when a change of colour occurred, it was fortunately for the better, the deep green merely changing to a bluish green. Instead of using two blinds only, like Mr. Fry, they used three blinds, one of them always being down, so that they only used two-thirds of the available light. As they worked at both ends, the blind was sometimes down at one end, and sometimes at the other. An acute angle in the roof had many advantages besides that immediately pertaining to lighting. It threw off the rain quickly, and so prevented leakage, and it allowed the rain readily to remove all dirt from the glass. There was a special advantage in

having the eaves low: ordinarily there was a dark portion, consisting of the top frame of the side light, the eaves, &c., just at the very point where the angle of light should fall on the sitter.

Mr. TULLY said the great difficulty of most photographers in large towns was, that they could not choose the position and character of their studios, but must make the best of circumstances as they found them. In his studio he found a great advantage in the use of sliding screens instead of blinds. These were covered with tisse paper, which was easily renewed. He had one of these screens covered with black linen, which would cut off all light. He also found it best to have glass on both sides, and secure shadow by the use of screens.

Mr. HARMAN had built his studio with glass on both sides. He could shut it out when it was not required, but as professional portraitists were called upon to take sitters in all weathers, it was desirable to have the power of admitting as much light as possible. It allowed him also to take Rembrandt portraits all round his studio, admitting or stopping out light from any point he chose. Sometimes he found an advantage in opening the blinds during a portion of a sitting, having previously cautioned the sitter not to be disturbed by such a step.

Mr. HOOPER said he worked in a studio originally built by Mr. Robinson. He had all his blinds quite opaque, so that he could, if he chose, turn the studio into a dark-room, or he could admit a small portion of light. He was satisfied of the advantage of working with a small aperture of light, but all that light reaching the sitter. In relation to reflecting screens, he thought it was important that they should be placed at precisely the same angle as that of the principal light, being practically parallel with the angle of the skylight, the upward reflections so secured relieving unpleasant shadows very much.

A general conversation followed, in which Mr. Fry referred to the advantage of the folding screen both as a reflector, and for admitting a softened light through semi-transparent muslin.

A conversation on the change of colour in glass followed, in the course of which it was generally stated that common glass answered best for studios. Mr. Fry had tried various samples by exposing sensitive paper under them. The sample which obstructed least light turned out to be a piece of common glass.

Mr. MORGAN again referred to the advantages of being able to remove a portion of the skylight entirely. He did this during the greater portion of the winter, removing part of the south roof. The weather did not seriously interfere, and the gain in exposure was very great.

After some further general conversation the proceedings terminated.

### AMATEUR PHOTOGRAPHIC ASSOCIATION.

A MEETING of the council of this society took place on the 9th inst., at 12, York Place, Portman Square; T. SOPWITH, Esq., M.A., F.R.S., &c., in the chair.

The minutes of the last meeting having been read and confirmed, the following members and subscribers were elected:—The Hon. Noel Waldegrave; K. D. P. Roberts, Esq.; A. Strohl, Esq.; G. M. B. Arnold, Esq.; R. O. Milne, Esq.; Capt. Jno. Houghton; J. E. Thornburn, Esq.; J. C. Stenning, Esq.; J. T. Hackett, Esq.; P. Gnyon, Esq.; E. R. Lloyd, Esq.

The secretary laid before the council a letter he had received from Capt. Allen, expressing a wish that the complete catalogue, for which a sheet containing the names of the best pictures only had been substituted the past year, might again be provided for use of the members. After some discussion it was decided that, since many other members had expressed the same wish to the secretary, the complete catalogue should again be printed, as in the previous years.

A. J. MELHUSH, Hon. Sec.

## Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF LONDON.—The meeting of this society, intended to have been held on the evening of Tuesday next, to consider the draft of the new laws, is postponed through unavoidable causes. We presume that due notice will be given to members of the time of the next meeting.

IDENTIFICATION BY PORTRAITS.—A curious illustration is given in the *Pictorial World* of the difficulty of absolutely identifying any one by means of portraits, unless all the conditions of familiarity are preserved. Copies of photographs, taken

before their conviction, are given of Macdonell and Bidwell, whose names will be remembered in connection with the great forgeries on various banks a few months ago. These are placed side by side with portraits taken in prison, after the shaving off of board and moustacho in each. Two gentlemanly and intelligent-looking men become converted into two sinister-looking, hangdog-looking fellows, whom no one would ever dream of identifying with their former portraits.

**THE PHOTOGRAPHER ON THE GOLD COAST.**—No public scene is now complete without the presence of the camera, and it seems difficult to find a region so inaccessible as to be secure from its invasion, or to discover circumstances so discouraging as to quench the ardour of the photographer. We read in a letter from the Correspondent of the *Daily News* that on the triumphal return of Sir Garnet Wolseley to Cape Coast Castle, he was so beset by those anxious to greet him that "it was with difficulty that a space round the carriage could be got clear to enable a photographer, who had been on the watch all the morning, to get his apparatus in order to get a view of the scene."

## To Correspondents.

**THE PHOTOGRAPHIC SOCIETY.**—Several correspondents write again on the subject of the Photographic Society. Some express their congratulations on the prospect of restored amity, and hope that the hard words on both sides will be forgotten, and cordial co-operation for the good of the society follow. Some write to suggest that there should be a complete retraction of the charges and insinuations against the council, and that all proceedings which have taken place, either in opposition to, or without the sanction and co-operation of, the council, should be considered null, all matters commencing again from the point of the resignation. One remarks:—"There are two positions which may be assumed: first, the *status quo ante bellum*. This is the only condition on which a perfectly good understanding and really harmonious co-operation can be secured. There should be no retention of grudges or unforgivable offences, which must result from a patched-up peace in which the gains of the agitation are retained by the agitators. The second position is that to which I refer in my last sentence, the *uti possidetis*, in which certain things have been secured during the absence of the council, and are not given up on reconciliation. If such a position could be accepted by the council with dignity, it certainly could not with cordiality." As we hope that a spirit of amity will be cultivated by both sides, and neither excessive demands nor unfair or churlish refusals will be made, it is scarcely necessary to discuss our correspondent's analysis of the situation. Another correspondent hopes that entire reconstruction may be the issue, and a really national society formed, in which outlying members shall have all the privileges of resident members, and especially hopes that we will continue to put a stopper on bitter tongues on both sides, which do an infinity of mischief. Two correspondents call our attention to a letter which appeared a few weeks ago asking if the funds were safe in the hands of the members of council elected at the annual meeting. Our correspondents suggest that this implies a doubt of the honesty of these gentlemen. The only suggestion which that letter bore to our mind was that, from lack of experience or prudence in the new council, the present surplus might easily be frittered away, and the difficulties out of which the late council had with much care retrieved the society be brought about again. As lack of prudence—not of honesty—brought the society into difficulties before, it was not an unnatural nor an offensive assumption to suppose that, under the charge of an inexperienced council, a similar state might be revived. Without altering our opinion of the wisdom of late proceedings, we should be unwilling to have given currency to anything which implied a doubt of the integrity of the actors therein.

**T. R.**—A rich black tone, like that of the print you enclose, may be obtained by several toning baths; but it does not depend entirely upon the toning baths. An imperative primary condition is a good negative with vigorous contrasts. With a brilliant negative and paper, and printing bath in good condition, it is not difficult to obtain rich black tones with almost any of the toning formulæ in use; but the lime bath is most favourable to the production of blacks. Take 3 grains of chloride of lime, 2 grains of chloride of gold, and 12 ounces of water. Mix the solution forty-eight hours before it is required for use. This will readily give black tones, and may be used over and over.

**D. M.**—The portable camera we devised and described many years ago has undergone many changes and improvements since then at the hands of the manufacturer, Mr. Meagher, who will give you every information.

**Z. Y. X.**—The minute yellow spots in the mounted print you enclose may have proceeded from one of many causes, but it is impossible to say which without tracing the history of the print through all the possibilities. The spots may arise from imperfection in the paper. Sometimes albukenized paper which has been long kept, especially if in a damp place, will undergo a change which produces such spots. They may be due to imperfection in the mounting board, which appears to be of a common kind. They may arise from a prolific but rarely suspected cause of trouble, namely, particles of hyposulphite in the atmosphere of the operating room. Hyposulphite solution is sometimes spilled, or small portions of the crystals themselves. Being ground under the feet of persons constantly walking about the room into an impalpable powder, particles are wafted about by every little draught, and come into contact with paper and prints, and often cause minute spots, the origin of which cannot be traced. The dust from a coke fire will sometimes cause such a result. The markings on the sensitive paper most probably arise from contact with some shelf or table not perfectly clean.

**S. C. FELL.**—There is no efficient way that we know of by which you can repair a cracked ebonite bath, nor any method by which you can efficiently cleanse it so as to prevent its contaminating the silver solution. After being in use for a time such baths very often produce a fogging condition, as does gutta-percha also. The safest material is glass or earthenware. To make the best of your cracked vulcanite bath, perhaps the best plan will be to take a strip of linen and cement it outside over the crack with mariole glue, and then give the inside a good coating of shellac varnish, which will aid in filling up the crack and giving you a clean neutral surface in contact with the solution.

**J. D. LYSAGHT.**—It is possible to precipitate the baryta salt from your bath by the careful addition of sulphuric acid, which will throw down sulphate of baryta; but there is some risk at the same time of forming traces of sulphate of silver. You may try with a small quantity. Probably the safest and simplest plan will be to precipitate the silver by means of copper or zinc, and, after washing well, reconvert it into nitrate of silver by treating the precipitated metallic silver in powder with nitric acid.

**M. A.**—The only mode in which you can avoid inhaling other fumes during the coating of large plates, so far as we can see, will consist in averting the face as much as possible, avoiding holding the nostrils directly over the plate, and keeping the room well ventilated. If you hold the plate as much at arm's length as possible, and as low down as possible, you will avoid the fumes considerably. We do not know of any protection to the nostrils you can use which would permit breathing, and would prevent other fumes from penetrating. Excessive breathing of other fumes will doubtless cause debility.

**WEST LIGHT.**—The permanent obscuration of your glass will doubtless be attended with difficulty, as it must make the light weak in dull weather. The simplest plan will consist in having an extra sliding-frame covered with white tissue paper, which can be placed over the glass when the sun shines, and removed in dull weather; or you will find the folding-screen covered with fine transparent muslin, or with the material sold by the stationers as tracing cloth, very useful. This screen may be placed so as to allow the direct sunlight to pass through the muslin before falling on the sitter. This will soften and diffuse direct sunlight, and need not be used in dull weather.

**F. T.**—The albumen used for preliminary coatings may be very dilute indeed; the white of one egg in a pint of water will answer. The best mode of applying it is by means of the Blanchard brush, which consists of a piece of swan's-down calico tied to the end of a strip of glass. 2. A fifty-grain iron solution may be used for development, but requires a little care in manipulation not to cause stains. About twenty minims of acetic acid would be sufficient. It tends to produce softness rather than intensity.

**ERRATA.**—In Captain Abney's article on "Dry-Plate Development," p. 128, second column, second line, for "adaptation" read "addition;" fourth line, for "my process," read "the process;" fifth line, for "extra," read "alkaline."

**TO ADVERTISERS.**—On account of the large number of Advertisements forwarded this week, the Publishers are reluctantly compelled to hold over some Announcements received later than those inserted.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### LORD LINDSAY'S EXPEDITION TO THE MAURITIUS.—HOW TO ESTIMATE ALBUMEN IN SOLUTIONS.—ROMANCE AND REALITY.

*Lord Lindsay's Expedition to the Mauritius.*—Early in June is the time fixed for Lord Lindsay to leave England for the Mauritius, attended by a staff almost as numerous as that which accompanied our English general to the Gold Coast. The object of the expedition is, however, a widely different one, although the benefits that will accrue from it will doubtless be more lasting. Independent of the observing parties sent out under the auspices of the Government and the Astronomer-Royal (of which we gave an account a fortnight back), Lord Lindsay acts entirely upon his own account in observing the transit of Venus, and will proceed to the station selected by him with a set of apparatus and body of assistants chosen by himself. The optical apparatus to be employed has been constructed by Mr. Dallmeyer, and may be considered the most perfect of its kind; and when we state that the length of focus of the lens—which governs, of course, the dimensions of the camera—amounts to thirty-eight feet, our readers can form some idea of the stupendous nature of the preparations that have been made. An untimely accident, which at one time bade fair to jeopardise the whole undertaking—viz., the fracture of the big lens—has fortunately turned out to be less serious than was at first supposed, the principal part, or sole of the lens, having been left whole, and the defect, therefore, reparable in time. Like Capt. Abney, Lord Lindsay has decided to abandon moist films, and employ only dry plates in securing his records, and he has now reduced the number of processes under trial to three, from which a choice will eventually be made. His early departure for the Mauritius will allow, it is estimated, about three months at that station to prepare and get accustomed to the operations to be performed, so that the whole staff, twelve in number, may be perfect in their duties on the eventful occasion. Lord Lindsay himself will be chief operator, taking the plates from assistants, exposing them, and handing them further to the development or packing room. The period of exposure will be ascertained by experiments undertaken for weeks previously, and an arrangement adapted to the lens will allow of any given period of exposure being given, from the five-hundredth to the tenth of a second. An electric recorder in connection with clockwork, which is put into action by a tread of the foot, will control the exposure, and only allow the plate to be uncovered for the period determined upon. Every tenth plate that is taken will be forthwith developed, the film covered uniformly with the solution by hand, and then immersed into a bath; the result obtained from time to time in this way will guide the exposure of the plates in the camera. The phenomenon will last about four hours and a quarter, and as the temperature at the Mauritius during the time will in all probability be about ninety in the shade, a relief party will probably be necessary in the course of the work. The operations at this temperature will, however, be much simplified by the employment of dry plates, but the development of these will still be a critical operation. The observatory is to be forty feet in length, and the gigantic camera, which will of course be of the nature of a telescope, will come a distance of seven feet into the building. As our readers know, the pictures obtained will show a large bright disc, representing the sun with a tiny dark spot upon it—Venus—the position of this latter varying with every exposure, from the moment when it first infringes upon the sun's limb until it has traversed the entire disc. The time of taking the different pictures will be recorded, and the results will serve as diagrams upon which mathematical calculations can be

made. In front of the sensitive plate will be a fine grating, which will also be photographed upon every picture, and these lines will aid very much in making the calculations subsequently. But how large will the sun appear in the photograph, it will be asked, and will Venus be really apparent upon the film? To most photographers the dimensions of the luminaries which will be secured may not be deemed large with such an exceedingly long focus, but those who are acquainted with photo-astronomy will be of a different opinion; indeed, no other observer, either in this country or abroad (unless it be Mr. Rutherford, of New York), will produce results of bigger dimensions. Lord Lindsay's disc of the sun will be four inches in diameter, while the little planet Venus, moving over its surface, will measure as much as one-tenth of an inch.

*How to Estimate Albumen in Solutions.*—It may be useful to photographers to know how to estimate the amount of albumen in various bodies, and a *modus operandi* of a reliable nature has just been made known by M. L. Girgesohn, which we will here quote. As a rule, photographers do not require their albumen in a chemically-pure state, but, at the same time, in a delicate process, which is being carefully tested, occasion may arise when the quantity of pure albumen in a solution requires accurate determination. The solution containing the albumen should be mixed with half its volume of a twenty per cent. solution of common salt, and a strong tannin solution is then added in slight excess. The precipitate is collected on a weighed filter, and washed with water till free of salt, and afterwards with boiling alcohol, until no more tannin can be detected in the filtrate; this latter is then pure albumen. The albumen of eggs, of serum, and like bodies, combines with twenty-eight per cent. of tannin.

*Romance and Reality.*—Photographers have much to answer for, and they ought to give the world thousands of pretty pictures to compensate for the many romantic charms they have broken. Take, for instance, the popular notion of Royalty as it existed a hundred years ago, and as it now is, based upon the evidence of a multitude of photographs. To be a princess in former days was tantamount to being exquisitely pretty, and "as charming as a princess" was quite an ordinary expression. There was no mistaking a princess in the good old times—they were always so delicate, fragile, and fair; and, indeed, in a story-book, we remember, there was an infallible recipe for finding out whether a person was a princess or not: it consisted simply in allowing her to sleep upon nineteen featherbeds, below the undermost of which was a grey pea; if she slept soundly, there was no Royal blood in her veins; but if, on the contrary, she was chafed, and passed a restless night, this was taken for proof positive of her noble origin. With the photographic portraits of to-day before their eyes, we fear the belief of our children will be shaken in matters of this kind. Then as regards kings and emperors, instead of being dressed as they were represented in prints and engravings, in magnificent robes and crowns and sceptres, our photographer shows them us as quite ordinary individuals, who sometimes wear a plain uniform, but generally affect a comfortable lounging suit and a cigar. One might, perhaps, forgive the absence of the crown, but surely the sceptre ought to be shown somewhere—either peeping out of a pocket, or laid aside on the mantelpiece for the moment. Fancy a child reading one of Hans Christian Andersen's fairy tales. "Come in," said the old king, when John knocked at the door. John opened it, and the old king came towards him in a dressing gown and embroidered slippers; he had the crown on his head, and the sceptre in one hand, and the orb in the other. "Wait a little," said he, and put the orb under his arm, so that he could reach out his hand to John." Think of a young scholar spelling through all this, and then being shown the portrait of the Russian Czar, or our Prince of Wales, or mighty Empress of India. He would at once have grave doubts about the story being true, and then

heaven forgive the photographer. Take away a child's world of romance, and you tear from him all his pleasures, all his happy day-dreams, all his castles in the air. And the cruelty of this cannot be defended for a moment, for he will come soon enough to know what a hard matter-of-fact place the world is. Fortunately, the chances are that the infant mind would sooner believe the story-book than the photographer, and stick to the more pleasant belief as long as it was able. There are, however, on the other hand, some people to whom photographs of Royal personages must afford unlimited satisfaction. We mean votaries of fashion, who are always in a state of mind as to whether a thing is fashionable or not. By people of this kind the series of Royal portraits issued from time to time must be regarded simply in the light of tailors' fashion prints, serving to show how they must regulate their dress. In the same way as Mr. Sapsea used to dress as the Dean of Cloisterham, so there are no doubt many who take high personages, as depicted in their photographs, for their models. They study the flourishes on the Queen's robe, and note the cut of the coat which the Prince of Wales wears. These things are to them of the highest importance, and to be successful in this matter is to them the great aim of life. Apart from all this, however, there can be no doubt that the photographer, in truly representing to us great people in their private life, has done much to bridge over that wide gulf which is supposed to exist between the grandee and the plebeian, and, by properly depicting those of high standing in the realm, has deepened the sympathy existing between the people and the heads of the State. This is abundantly proved by the ready sale which the portraits of popular princesses and princes command at the present time.

#### FRENCH CORRESPONDENCE.

IN one of my last letters I expressed great satisfaction at the creation, in Paris, of a photographic mutual benefit society. This week I have assisted at a general meeting of the members, and I have now not the least doubt in the world of the future of the association, notwithstanding the many vicissitudes through which it has passed since its establishment. At the present moment it numbers more than one hundred and sixty members, and many candidates are now awaiting admission into the society. Before very long, all the employés of the Paris houses will deem it a point of honour to become members. Notwithstanding the losses to which the society has been submitted on its establishment, it has at present funds sufficient, not only to meet its engagements, but to make some necessary sacrifices in the general interest. In a little while the society will have its own place of meeting, instead of assembling in a public room as at present. The meeting which I recently attended demonstrated to me that there existed a capital understanding between the president and members, and a general good feeling throughout was manifest.

Not only, I would point out, is this institution indispensable for photographic employés, who, as a rule, are well remunerated, and may, therefore, easily spare a contribution when in full work to put by for a rainy day, but the society completes the work undertaken by the French Photographic Society, and the *Chambre Syndicale*, composed of master photographers. All interests are now represented by special associations, and there only remains now for all three to fraternise mutually.

M. A. Liebert has this week published the second edition of his "Traité de Photographie." Although the work carries still for its principal title "La Photographie en Amérique," it embraces the practical details of processes carried on in every country.

M. Liebert, who has now practised the art for upwards of twenty years, enjoys a very large experience; he has

been well trained, and his intelligent and active mind is seconded by a ready pen. These qualities are precious ones when it is a question of preparing a work of this nature. For this reason the work I allude to is very certain to obtain a good reception. I believe, even, it will create a sensation, for the author, who has studied the processes with care, has neglected nothing to render them intelligible to his readers. His volume is illustrated by many illustrations of singular interest. The first is a very fine portrait of the author; then come four pictures upon one page, reproducing the different effects which may be obtained by the Rembrandt mode of lighting. Two portraits, cabinet size, follow, showing the difference which may exist between two clichés, one of which has been retouched and the other not. Finally, in illustration of the chapter on Heliographic Engraving, there is annexed a charming portrait engraved by the Rousselon process. The other prints are all produced by the Woodbury process. The illustrations are, therefore, of interest from every point of view; many woodcuts are, moreover, scattered through the volume explanatory of the text, which is thus rendered very intelligible.

The police authorities in Paris have decided to utilise the resources which photography offers for recording the features of convicts and gaol birds. For some time past, exertions have been made to collect from photographers portraits of all those who busied themselves with the Commune. These have been reproduced, and copies distributed to the various police stations of the metropolis. Now-a-days, every one sent to prison is photographed, and his picture kept for future reference. I am told, even, that there is a likelihood of passports, shooting licenses, and such like documents having in future to bear the portrait of the owner, it being notorious that the signature alone is of little value.

These tasks are confided to an operator belonging to the administration in connection with the police, so that there is no fear of any indiscretion or delay arising, such as would be very possible in the case of a stranger being charged with the duty.

And here I may remark a fact which is of significance: that there is scarcely a meeting held of the Academy of Sciences without photographic prints of some kind being produced by scientific men desirous of supporting their communications by means of authentic documents.

M. le Comte de Courten has forwarded to me some interesting observations upon a matter which for some time past has been under discussion, and which is at the present moment the object of general attention, viz., the spots which become manifest upon pictures printed with silver salts. Like MM. Rohaut and Hutinet, the skilful amateur I have named is of opinion that the cause of the defect must be sought for elsewhere than in the cardboard used for mounting the pictures. M. de Courten has remarked that pictures mounted upon cards with gold margins almost always alter in this way. The margins of gold are produced by means of Dutch metal, or, chemically speaking, with bisulphide of tin. It is applied to the cardboard by means of a fatty ink, or gold-size varnish, which is printed upon the card, the powder being afterwards applied by means of a dry brush. The metal or bronze attaches itself only to the size, but there remain very fine particles, almost invisible, all over the surface, which the most careful rubbing or cleaning will fail to remove. M. de Courten believes that every particle of metal remaining upon the card serves to produce a minute spot upon the photograph mounted thereupon, and he explains in the following manner the formation of the defect. There is produced, he says, a sort of galvanic action, on the one side being the bisulphide of tin, and on the other a film of silver forming the photographic image. The thickness of paper plays the part of a porous diaphragm. If the print has been strongly fixed, and has received afterwards

but insufficient washing, traces of the fixing salt are left in the pulp of the paper, and this then becomes the best conductor of the galvanic action which is established between the two metals thus placed in communication with one another.

SPOTS, STREAKS, AND STAINS.

BY F. WALLER.\*

THIS article proposes to point out some of the effects and defects liable to occur in the making of negatives; their cause and cure.

Pinholes are little fine spots, like sand scattered evenly over the plate, which are transparent after the negative is fixed. Cause: overworked bath. Remedy: add silver to increase the strength, or add water, filter, and boil to proper strength. Temporary relief may be had by taking the plate from the bath immediately upon being coated.

Particles of undissolved excitants in collodion will also give a very similar pinhole, but generally not so numerous and large. Remedy: careful filtration.

Comets, or spots with little tails, proceed from dirt in the collodion, upon the plate, or dust in the holder or instrument. Care will obviate these.

Circular spots in the shape of rings occur where water has splashed upon the albumen surface of the plate.

Circular opaque spots are caused by excess of acid in bath or dirt on the glass; new samples of glass will often produce this disorder.

Spots are also caused by the slides being drawn too rapidly and splashing the plate, by particles of old film being left upon the plate, by bubbles in the collodion, and by floating particles of dirt in the bath.

Streaks are produced by the collodion not being well set; these show most at the thick end of the plate, or by the collodion being over set, which shows at the thinnest end of the plate; by stopping the plate in immersing it in the bath; by immersing it too rapidly, causing waves from the dipper; by not being coated enough, which produces hair lines running the same way the plate was dipped; by the bath not being sufficiently iodized, which will cause alternate opaque and transparent lines, running the same way it has lain in the bath.

Streaks are also produced by too strong a developer, when they will appear as more dense marks, running straight from where the developer was poured on. Fixing in cyanide will produce streaks which show more on the back of the negative.

Streaks are caused by imperfect flowing of the collodion, or when it is too thick; they will appear as ribs running toward the end the collodion is run off of.

Network streaks occur from the presence of water in the collodion.

Over-iodized collodion will give zigzag markings. Too strong redeveloping solutions will also give streaks or an acron density to the negative.

Stains are caused by dirty glass, or by dirty fingers in contact with the plate, by not wiping the corners of the holders, by not dripping the plate enough, by holding it up to look at before washing off the developer, by not washing off the developer well before fixing, or by not washing the hypo well away afterward.

Fogs are caused by overtime; by undertime and forced development; by light leading into dark room, camera-box, or holder, or by reflection in the tube; by want of acid in the bath, and by excess of it; by the bath not being iodized, by the developer not having acid enough in it, or by being too strong or weak by alkaline collodion. All fogs from light are easily discerned, as they are opaque; and all chemical fogs, except from dirty glass and excess of acid, can be rubbed away with the finger. With pure chemicals and care, any or all of these troubles should give but

momentary difficulty. Cleanliness will cure all streaks, spots, or stains, and convert any streak into one of good luck.

THE REPRODUCTION OF NEGATIVES.

BY J. OBERNETTER, OF MUNICH.\*

A TRUSTWORTHY and easy method of multiplying negative in such a manner that the reproductions are in every way equal to the originals is a matter that has occupied me for a period of ten years. I have tried copying by means of the camera and by dry plates, and obtained in this way good positives; but the negatives produced again from these positives were bald and hard, and it has never happened that I have been successful in securing a printing cliché by these means which has satisfied me. Collodio-chloride gives excellent results, and by its assistance I have obtained negatives which yielded prints quite equal to the originals; but regarding the trouble and time they cost me, and the long period I had to wait until I secured a good result, I will be silent.

In the year 1870, when the war allowed me a little time for experiment, I set about following out an idea of my own, to attain the object of my desire by means of the powder process; and in 1871 I was enabled to perform a very heavy task, wholly and alone by this method. At that time I employed silver as the material for powder, such as is secured when old silver baths are precipitated by means of sulphate of iron solution; while for preparing my sensitive mixture I made use of a very complicated formula.

By practically working out the method in my own studio, and employing it in my business, I have succeeded in rendering the *modus operandi* very simple, and may say, with a good conscience, that the process is really to be recommended. In my own business the method has been constantly worked for three years, and upwards of 2,000 negatives have been reproduced by it, and may be viewed by any one interested. The largest cliché has a diameter of seventy centimetres.

An examination with the naked eye would not tell even the most practised photographer that they were not silver negatives; the paper prints produced are quite as perfect as those from the original negatives. I may go further, even, and say that from a negative which is too dense, and requires a day or two to print, another may be produced which will yield quite the same kind of prints in the ordinary time; and in the same way it is possible to produce from a comparatively flat negative a vigorous one. From every negative, moreover, may a serviceable enlarged cliché be produced.

The method is not a complicated one. Difficulties from the chemicals employed cannot arise. Some manual skill is necessary, but by practice and industry everyone, whether photographer or not, may learn to carry out the manipulations perfectly. Here are the details of the matter. A new, well-polished patent plate is poured over with the undermentioned solution, in the same way exactly as collodion:—

Dextrine	...	...	4 grammes
Ordinary white sugar	...	5	"
Bichromate of ammonia	...	2	"
Water	...	100	"
Glycerine	...	2 to 8	drops.

After a complete solution has been made, it is filtered. The preparation will keep good for several days. The plate having been coated, and the superfluous liquid poured off at one corner, it is placed in a horizontal position, and in some place free from dust, to dry, in a temperature of about 40° to 60° Reaumur. After a period of from five to ten minutes, the solution dries with a mirror-like surface. Whilst still warm it is put into an ordinary

\* Photographer's Friend.

\* Photographisches Correspondenz.

pressure-frame under the negative to be reproduced, and exposed to diffused daylight, according to the density of the cliché, for a period varying from five to fifteen minutes. If the exposure has been well timed, the picture appears slightly visible upon the film. After the plate has been withdrawn from the printing-frame it is again put into the drying oven, where it remains until it has become a little warmer than the atmosphere of the room in which the next operations are carried on. When the plate has reached this temperature, it is carried into an apartment not too much lighted, upon a sheet of white glazed paper. A fine dusting-brush is dipped in the finest levigated graphite, and this is rubbed carefully over the plate. Breathing upon the plate renders it more capable of attracting the powder. When the desired vigour has been attained, the superfluous powder is dusted off, and the plate is coated with normal collodion, made up of—

Alcohol	...	...	...	500	parts
Ether	...	...	...	500	„
Pyroxilin	...	...	...	20	„

Afterwards the film is cut through at the margins of the plate by means of a sharp knife, and put into water. In a little while—from two to five minutes—the collodion with the image will be detached from the glass; the film is at once turned over in the water and brought out upon the glass plate. Under a soft jet of water any air-bubbles that may exist between the collodion and the glass are removed, and then the image is poured over with a thin solution of gum-arabic (two grammes of gum dissolved in one hundred grammes of water), and allowed to dry spontaneously in an upright position. After drying, the plate may be varnished in the ordinary way. Upon the theory of this method of working, it will, I think, be unnecessary for me to enter; the matter is known sufficiently well, and I shall confine myself, therefore, to adding a few remarks on the subject. The addition of glycerine is employed by me in order to suit the solution to the different conditions of moisture in the atmosphere. Thus, in a moist, warm atmosphere, in summer, the solution does very well without any glycerine at all; while in winter, on the contrary, in a cold, dry atmosphere, the addition of from eight drops to one hundred grammes of the mixture is necessary. Practice will soon teach the operator how much is really necessary.

The right kind of graphite to employ is one of the main things to be attended to. With every kind of material—even the worst—serviceable negatives may be produced, but it is only one particular description which yields clichés such as are not to be distinguished from silver negatives. This is the genuine Siberian graphite, very finely levigated, prepared by Faber at Steiu, near Nuremberg, costing six florins a pound.

The printing is easily performed, for the limits are wide. During the operation of dusting on the powder much may be remedied. Too short an exposure in the printing-frame gives a fogged picture, too long a one a hard one.

As regards a large number of practical applications of this process, I hope, in a short time, to make a further communication. But very lately I received from Berlin some negatives of great value for reproduction, all of which had been produced upon very uneven Rhinish glass. In printing, I found my reproductions looked sharper, and I dared not use any great pressure, for fear of breaking the plates. I overcame the difficulty by employing mica plates, and transferred the film afterwards to other glass plates. Mica plates will lie quite close to an uneven glass surface, and by its aid it is possible, therefore, to reproduce negatives taken upon inferior kinds of glass.

## INTENSIFYING BY ATMOSPHERIC PRESSURE.

BY J. CASTELLANI, OF ALESSANDRIA.\*

ALREADY last year I had made up my mind to communicate a new process for intensifying negatives, but eventually postponed doing so, as I was not quite sure of my results. But now I am again reminded of the subject by M. Krüger, of New York, who has made known a method of operating analogous to the one I practise.

At the commencement of last winter it was my duty to secure a photograph of a horse. It was very cold at the time, so that I was fearful lest the silver solution upon the plate might freeze. It did not matter how rapidly I worked, there was always to be seen upon the film a grey crystalline formation, and no details in the shadows could be secured. The restless nature of the horse did not permit of a long exposure being given, and I then endeavoured, by breathing upon the film during development, to thaw it in some degree. What was my astonishment to find at once that the picture developed clearly and vigorously. On returning home I forthwith began to test my discovery further, breathing, or rather blowing, upon my plates during development. I did not obtain any uniform results, but found, nevertheless, with every experiment, that the duration of exposure might be shortened with this method, and the vigour of the picture augmented.

Since then I have always employed this plan when I have been compelled to give short exposures, and when I desire to invigorate certain details in a picture. I proceed in the following manner:—When I have a rapid exposure to give—whether it is a child, a dog, a horse, or what not, to photograph—I coat my plate with collodion prepared according to the undermentioned formula, viz:—

Cotton	...	...	...	12	parts
Ether	...	...	...	500	„
Alcohol	...	...	...	500	„
Iodide of ammonium	...	...	...	5	„
Iodide of cadmium	...	...	...	5	„
Bromide of cadmium	...	...	...	5	„

In the bottle I invariably put a strip of polished cadmium, which will maintain the collodion in a colourless and unchangeable state. The collodion must be at least a week old before it is employed.

My silver bath is thus prepared:—

Nitrate of silver	...	...	...	30	parts
Water	...	...	...	500	„

A little nitric acid is added, just sufficient to give the solution a slightly acid reaction. The nitrate of silver I always recrystallize and fuse twice. In this way I obtain it in a perfectly pure state.

My developer is composed of—

Rain or distilled water	...	...	...	1000	parts
Double sulphate of iron and ammonium	...	...	...	50	„
Acetic acid	...	...	...	10	„

Alcohol as much as is necessary to make the developer flow evenly.

I intensify but very seldom by chemical means, as by breathing or blowing upon the negative I secure any degree of vigour. I expose very briefly, pour the developer upon the plate, and then blow through a glass tube about half a centimetre in diameter, in the upper end of which a small stopper of sponge is fixed to prevent any moisture from the mouth reaching the plate. A little experience will soon show how strong it is necessary to blow in order to obtain uniform vigour in a negative. If the blast is too weak, the action is insufficient; and if it is unequal or too strong, then the result is not uniform, and ugly patches are formed. In this way I am enabled to obtain clear and vigorous negatives full of detail.

If I desire to intensify more particularly certain portions of a negative, I use a hollow india-rubber ball, which is

in communication with a glass tube. By pressing evenly upon this ball I impel a blast through the tube, which is directed against any portion of a negative which it is desired to render more vigorous. So that I may be able to watch the effect of the air upon the plate during the operation, I have a looking-glass properly fixed, which readily shows me the change produced. I should remark, however, that this method of intensifying has its limits, and cannot be employed, for instance, in securing dense negatives, or drawings in which the lines are desired perfectly transparent and the ground opaque. For ordinary work—portraiture and the like—the required intensity may, in most instances, be secured by this plan of operating, and without having recourse to any working up of the cliché by chemical means.

A CONVENIENT AND PORTABLE CAMERA.

BY GEORGE BARNES.

THINKING that perhaps the following description of a camera I use might be useful to some of your amateur readers, I send it to you.

The chief points of merit in my camera are, I think, these:—It is very light, very cheap, and will pack up into a small compass, so that a wallet about 14 by 12 will contain everything necessary for exposing three or four half-plates.

The base of the camera (fig. 1) is a piece of inch oak,

about three inches wide and fourteen long, having a slit (B B) cut each end, in which runs a thumb-screw to fix the front and back securely; c c c c are pieces of grooving screwed on. In this grooving run small blocks of oak, to

which the front and back are screwed (fig 2, and dotted lines in fig. 3).

The front of the camera consists of a piece of three-eighth inch oak, with grooving and sliding front to which lens is attached. The back is a piece of half-inch ditto, with

groove for dark slide to fit in. To each of these are screwed, in the portion shown (c c c c, fig. 3), small blocks, notched, over which the body of the camera fits. The body is made of cloth, with yellow lining inside, having a piece of wide elastic run through each end to draw it over the four projecting pieces, which are connected together with strips of cloth, to more effectually exclude the light. The body should be made about the right length for the focus of the lens; if, however, as in my case, different lenses are likely to be used, it can be folded in the middle as required.

The dark slide (fig. 4), as also the focussing-screen, fits

in from behind. It consists of a piece of  $\frac{5}{16}$ -inch oak  $7\frac{1}{4}$  inches square (it is made square, so that the pictures may be taken either way, vertical or horizontal). A hole is cut to size of plate,  $6\frac{1}{2} \times 4\frac{3}{4}$ , and silver wire put to corners. On the front of this is screwed a flap and frame, the flap being rather thinner than the frame, to prevent it coming down on plate. A rebate must be left all round, corresponding to that in camera-back. The frame is double-grooved, to prevent the light getting in.

On the back is also screwed a flap. This need not have a frame, but simply a piece to hang it to, and button to keep it closed. The dry plate is placed in the slide, a piece of thick black cloth at back, and a piece of thick pasteboard behind this. The flap is then shut down, and it is simply impossible for any light to get in if only the cloth and pasteboard are cut the exact size. To expose, the front flap is opened by means of a piece of bent hoop iron in this shape  the part A being screwed to top of flap, and A B B passing through to back of slide; then, by pulling down the part c, the front flap is opened up, and kept so by a little bolt. The flap is kept shut till just before putting into camera-back by a small button; then, by placing the thumb against part C of crank, there is no fear of it opening before its time.

The light is kept from passing through the hole made for crank by a piece of yellow lining glued inside and tied round same. The focussing-screen is the same as dark slide, only without the back or front flap, so that the ground glass and sensitive plate are necessarily in the same plate.

The whole of this camera, including dark slide, I do not think cost me more than a pound; but as I made some of it myself, I cannot correctly tell.

Should any of your readers think of trying this camera, I shall be happy to give them any details concerning it, or give them the address of the man who made mine, and who, therefore, understands it.

Some may, perhaps, rather doubt an amateur dark slide, but I have used mine for two years, and never had any fault to find.

I find it more convenient to carry the base-piece screwed to the camera-stand.

## THE ACTION OF LEAD SALTS ON SILVER PRINTS.

We have received some further communications on the action of lead salts on prints. Referring to the remarks in our last, Dr. Diamond reminds us that at the time to which Dr. Anthony refers, many calotypists used the lead salts for the double purpose of removing the final traces of hyposulphite, and improving the tone of their prints, a fine warm velvety black being obtained by its use. In Dr. Diamond's experience, the final issue was rarely satisfactory, the traces of lead left in the paper generally leading to discolouration of the whites after the prints had been for some time exposed to the atmosphere, which always contains traces of sulphur compounds in greater or less proportion wherever coal fire or gas illumination is employed.

In a communication from Mr. Gregson, it will be seen that his experience is wholly in favour of the use of the lead salt.

Another medical correspondent, whose letter we publish this week, again refers to more satisfactory experience, prints treated with the acetate of lead having withstood a trying ordeal, in the shape of exposure, without change. There are two facts of importance to be borne in mind in connection with the latter experience: the first is, that the atmosphere to which the prints have been submitted is probably much less charged with sulphuretted hydrogen, or other sulphurous vapours, than that of a large town; and second, that the prints have been exposed to light as well as air. The action of sulphurous vapours upon lead salts is of a darkening character, as is well known; but the action of light upon lead salts so blackened is of a bleaching character. Lead salts, when exposed to the action of sulphuretted hydrogen, rapidly blacken in the dark; but exposed to light, a bleaching action is produced by the light. Hence prints containing traces of a lead salt kept in a portfolio, whilst protected from light, but not sealed from atmospheric action, will probably change more than similar prints exposed to the full action of light. The difference in the condition of prints simply washed and treated with the lead salt appears to be this: simply washed prints may, unless very especial care be used, contain traces of hyposulphite of soda and silver, the presence of which will almost inevitably produce subsequent change. The use of the lead salt will secure the absence of these substances, but may leave traces of an insoluble salt of lead, which will darken under the action of sulphuretted hydrogen. If, after the use of the lead salt, the prints be well washed, a

little nitric acid being added to one of the washing waters to aid in removing the insoluble lead salt, there is probably no bad result to be feared. Whether greater safety will be more readily secured by its use than by very perfect washing, aided by mechanical pressure, will probably still be considered an open question.

It may be well to remind amateur experimentalists that the salts of lead are very poisonous, and that the absorption throughout the skin of a very small proportion is sufficient in some constitutions to produce an attack of painters' colic.

## BENGAL PHOTOGRAPHIC EXHIBITION.

THE recent photographic exhibition in Bengal appears to have been a success, and it is interesting to find the appreciation of the press and of the medal jury in this country, in relation to the works of various photographers, echoed in many instances in India. The medals given by the Bengal Photographic Society are probably the most liberal which have at any time been offered to photographers, and notwithstanding the residence of many skilful photographers in the Presidency, the lion's share of the medals generally find their way to this country.

The Viceroy's gold medal was awarded to Messrs. Robinson and Cherrill, for their fine composition, "Preparing Spring Flowers for Market"; and the second gold medal was awarded to the same artists for a series of figure studies. The silver medal for the best series of landscapes taken out of India was awarded to Mr. F. Beasley, for a series of views taken on dry plates. Captain Abney's pupils, the School of Military Engineering at Chatham, obtain an extra silver medal for a series of views at Windsor. Mr. G. L. Kemp obtains a silver medal for a series of views in Upper India. Messrs. Bourne and Shepherd receive a gold medal for Indian landscapes and architecture, and a silver medal for photographs of Indian antiquities. A silver medal is awarded to a series of fine pictures by the Woodburytype process. A silver medal was awarded to a fine series of photo-collotypes exhibited by the Photographic Branch at the Surveyor-General's Office, which is under the charge of Captain Waterhouse. Mr. Marshall Wane receives an extra gold medal for his charming examples of portraiture. Messrs. Bourne and Shepherd receive the silver medal for the best portraits taken in India. A silver medal for portraiture is awarded to Messrs. Westfield, as resident photographers. A silver medal for portraiture of an Indian subject was awarded to Dr. Brown, an amateur resident at Mauipur. Mr. England's admirable photographs of statuary also received a silver medal. Major H. L. Millett obtains a bronze medal for a collection of views on Chamba.

The *Calcutta Englishman* devotes considerable space to a careful and apparently discriminating criticism, a few extracts from which may interest our readers. Mr. Crawshay's munificent prizes have had their influence, it seems, in the exhibition in Calcutta. We learn that—

"In portraiture, as might be expected, the finest specimens are from England, but the local contributions are unusually numerous, and many of them are in their way quite equal to the best work done in Europe; and we imagine that, besides the difficulties connected with the climate, one cause of the deficiency of large specimens from our local artists is the want of an appreciative public who are prepared to pay highly for such productions. The English contributions are not so numerous as last year, but it is noticeable that the influence of the prizes offered by Mr. Crawshay for the best portraits of large size, taken direct or enlarged, is very marked, and the majority of portraits sent out this year are either full or about half life-size. That this is a move in the right direction there can be no doubt; but as yet the results cannot be considered quite satisfactory, though we note a great improvement, which will doubtless be further stimulated by the renewal of Mr. Crawshay's munificent offer."

Referring to "Preparing Spring Flowers for Market," which we are told "most deservedly gains the Viceroy's

gold medal as the best picture in the room," the *Englishman* says that it

"Is certainly a masterpiece of photography, exceedingly perfect in all its details, and forming a most pleasing picture of an English cottage interior. Seated at a table strewn with flowers is a comely English peasant lass busily engaged, as the title of the picture implies, in making up bunches of flowers for market, while another, having filled her basket, stands by, apparently in conversation with a third person not in the picture. The floor is strewn with baskets of flowers, vegetables, and other produce of the market garden. The cottage accessories are in perfect keeping with the scene, and come out just sufficiently distinct in the deep shadow surrounding the central group, which is brought into prominence with admirable skill by the light coming from a lattice window in the side of the cottage, and lighting up, in its way, the pots of blooming azaleas and other delicate plants brought in for shelter from the nipping frosts of early spring. The picture is of unusually large size, and the photography throughout very perfect. We cannot speak too highly of this triumph of composition; even the most conservative supporter of pure and untouched photography must admire the artistic skill and ingenuity that have been brought to bear in conquering the difficulties attending the production of such a picture. Several of our friends have asked us if it was really a photograph, and not a copy of a painting. No higher testimony to the art qualities of this splendid photograph can be needed. We only regret that it has not been printed in carbon, and its beauty thus rendered imperishable."

Referring to the views by Mr. H. Beasley, which are commended not only for their excellence, but for the information conveyed with them, in the appended note, of the process by which each was taken, the times between preparation and exposure, and between exposure and development, with other information regarding it likely to be useful to photographers, it is added that the writer has seen little wet-plate photography to surpass them."

Referring to the contributions from the Engineers at Chatham, the writer says:—"The whole series is excellent, and reflect great credit on the instruction given to the military photographers, who are sent from Chatham to all parts of the world."

Mr. England's Swiss views are very highly praised, and the Indian views of Mr. Kemp are commended, as showing how relief and picturesque effect may be gained by the judicious printing in of cloud effects, instead of the blank white spaces usually representing sky.

The well-known excellence of the Indian landscapes by Messrs. Bourne and Shepherd falls somewhat short, it would seem, in this exhibition.

"Though still superior to most Indian landscape photographs, we miss the soft brilliant delicacy and artistic treatment that characterised the earlier series by this well known firm; and although the present series are most interesting as illustrations of the scenery and architecture of little-known parts of India, with few exceptions they fail to please as pictures."

Speaking of some magnificent enlargements by the Autotype Company, they are described as among the finest pictures in the room, and regret is expressed that they were not for competition, or they would most undoubtedly have taken a very high place.

After a detailed notice of the examples of mechanical printing, the writer says:—

"The whole of these specimens of permanent printing—autotypes, heliotypes, Woodburytypes, and collotypes—are particularly worthy of attention, as examples of methods that are making rapid strides towards the complete extinction of the old and unstable processes of silver printing. While the silver printing remains the same, every year sees improvements in these processes, and a diminution in the obstacles and difficulties that hinder their general adoption. We look forward to the time when silver prints shall be the exception instead of being the rule."

Mr. Marshall Wane's portraits are highly appreciated, but Colonel Wortley's bold style does not please the writer, although the examples received honourable mention. Captain Swiney's examples of combination printing are commended, but regarded as less successful than the examples

exhibited last year. Mr. Hubbard's "Stolen Moments," and "Think it Over," which received honourable mention, are much admired. The notice concludes with an appeal to resident photographers to do fuller justice to the comparatively untrodden field of Indian specialities, and show results at the next exhibition.

#### A CURIOUS EXPERIENCE IN DEVELOPING.

OUR readers will find on another page an article by Signor Castellani, describing a method which he styles "Intensifying by Atmospheric Pressure;" the operation to which he refers consisting in blowing upon the plate during the process of development, and by so doing practically augmenting the energy of the developer. The statement at first sight seems curious enough; but we have no doubt that, with due qualification, it is strictly true, and that the experience of many photographers will confirm that of Signor Castellani. Many readers will remember that during the tardy development of a plate they have blown upon some patch of obstinate detail which failed to come out, with the half instinctive notion that forcing the developer into more intimate contact with the film by blowing would hasten the operation. And no doubt, whatever may be the cause, the desired result does follow. Mr. Robinson has more than once described an analogous operation which he employs for local intensification. If a portion of a background is required somewhat lighter than the rest—or if, in short, the light and shade of the picture generally can be improved by a patch or streak of light—he produces the result by pouring the developer or intensifier repeatedly upon the portion of the negative in which the extra light is required, and the forcible contact produced by pouring gives the increased intensity desired. Mr. Lake Price recommends, for securing local intensity, the use of a dropping bottle containing silver solution, by which a few drops could be applied to a special part of the negative. It is probable that the plan of blowing might be systematically employed, for securing local intensity, with advantage. An india-rubber ball with a tube might be kept at hand, and, if used with skill, various modifications of the light and shade of a picture secured by its use. The experiment is, at any rate, easy; and but one precaution is necessary: the india rubber must not be vulcanized.

#### DR. SCHNAUSS ON GILL'S CHROMO-INTENSIFIER

In the *Photographischis Archiv*, Dr. J. Schnauss gives the results of an examination he has made of Gill's intensifier, an American production, which the inventor states should be applied after the cliché has been fixed, the operator taking care only to secure a well detailed and a harmonious result, and relying upon obtaining the necessary vigour subsequently, by an application of the intensifier. The advantage claimed for it is that it does not render the image more dense, but only changes its colour. Thin negatives treated with it have the requisite printing opacity imparted to them, the vigour being acquired, it is stated, without any loss of harmony or softness.

Dr. Schnauss tells us that the chromo-intensifier is a clear yellow fluid, perfectly odourless, possessing a slightly acid reaction, and precipitating, particularly in daylight, a brownish red substance. On evaporation no smell is perceptible, and there remains a brownish red residue, which, heated more powerfully, carbonizes, developing an odour of cyanogen or prussic acid. The residuum ash has a strongly alkaline reaction, and contains much oxide of iron.

Caustic potash and ammonia produced in the liquid a yellow precipitate, which, in the presence of an excess of the precipitating body, became insoluble, which is characteristic of the oxygen salt of uranium. With oxide of iron salts the fluid gave a dark blue precipitate.

There can be no doubt, therefore, Dr. Schnauss considers,

that the chromo-intensifier is no other than the Selle intensifier, consisting of ferricyanide of potassium (red prussiate of potash) and nitrate of uranium, which we have here sailing under American colours.

### ALKALINE SILVER DEVELOPMENT.

BY CAPTAIN W. DE W. ABNEY, R.E.

In a recent note on alkaline development I pointed out that certain organic matters acted as restrainers, though not as destroyers, of the image. At that time I was experimenting with alkaline solutions of silver, having imagined that the introduction of silver would conduce to density, whilst the rapidity of the plates need not suffer.

Chloride of silver dissolved in ammonia was firstly tried on dry plates containing but a small proportion of bromide of silver. The sensitive surface being almost entirely composed of iodide, as a rule, on developing such plates by the alkaline method, but little density is acquired; in fact, merely a thin image is obtained. By using the ammonio-chloride of silver, however, a picture of printing density was easily gained. This led me to suspect that some change must have taken place in the film. In order to test this, a plate was developed and not fixed. Half of it, after thorough washing, was flowed with ammonia. On testing, a copious precipitate of chloride was obtained, and the shadows of the unfixed picture showed a corresponding diminution in density. The other half, when exposed to light, blackened as chloride of silver does. After repeating the experiment I have come to the conclusion that in the shadows the chloride was deposited in or substituted for the iodide. No trace of chloride was visible in the high lights. The plain pyrogallie acid which formed the developer, on the addition of the ammonio-chloride of silver, invariably produced a muddiness, as might have been anticipated. This left an unfavourable impression on my mind, as, with other photographers, I like clear developing solutions. A point worthy of remark is that, after a short application to the plate, the pyro became perfectly right, and, on testing, no trace of silver was to be discovered.

I next tried a saturated solution of chloride of silver in hyposulphite. To this a small quantity of ammonia was added, and was then employed in a similar manner to the ammonio-chloride of silver. The results were the same as regards density. On treating the film of an unfixed but well-washed plate with ammonia, an orange colouration was produced, and in the solution, again, were more than traces of chloride of silver. Probably the chloride of sodium in the solution converted the iodide partially into bromide. The plates developed perfectly free from fog, and with detail in proper gradations. The results obtained seem to me to be capable of application if further experiments by independent observers prove that they are not exceptional. An iodized film is much more opaque to actinic rays than a bromized film, and consequently less liable to blurring. If alkaline development be adopted for such plates, the introduction of the alkaline silver will give density.

The rationale of the process is the same as that I published two years ago, when I stated I thought density was often obtained in alkaline development by the ammonia holding in solution a small quantity of bromide of silver. In the above procedure the chloride takes the place of bromide. I shall be glad if others who are working in the same direction will try similar experiments, especially with the hyposulphite solution.

### ON DRY-PLATE DEVELOPMENT.

BY REUBEN MITCHELL.

HAVING read Captain Abney's remarks on dry-plate development, I can fully endorse his opinions expressed in his article in the News of March 13th, 1874.

About three years ago, after many experiments with a variety of developers, I fixed on one very simple, but very

satisfactory in my hands. I discarded bromide altogether, as useless and injurious.

My *modus operandi*. I do not content myself with simply wetting the surface of the plate before development, but give it a good washing under the tap. Place the plate on a holder, and have a three-grain solution of pyro filtered, and a dropping-bottle with strong liquor ammonia at hand. Take a developing cup, and pour as much of the three-grain pyro in as will flow on the plate, rock it backwards and forwards a few times, and return it to the cup; add one drop of ammonia from the dropping-bottle, and add more pyro—about as much as will flow the plate well. To prevent marking, keep it moving from end to end till the whole of the detail is fairly visible; then wash off the ammonia well from both sides of the plate, if the film will allow it without danger of injury. If any risk, wash with care, and flow the surface with a little of the pyro solution, to neutralize the ammonia.

#### Intensifying solution—

Nitrate of silver ... ..	20 grains
Citric acid... ..	20 "
Water ... ..	1 ounce

in a dropping-bottle.

Take a clean cup with as much of the three-grain pyro solution as will cover the plate, flow it on and return it to the cup, add one or two drops of the acid silver, and return it to the plate. If the exposure has been rightly timed, the development will soon be complete.

I have successfully developed dry plates with the above, prepared by a variety of formulae, without the slightest taint of fog.

### A METHOD OF PRODUCING COLLODIO-CHLORIDE FILMS.

BY CAPT. W. DE W. ABNEY, R.E.

It has often happened that I have wanted a collodio-chloride film when I had no emulsion by me, and I have always found that the introduction of a soluble chloride into the collodion, and subsequent immersion in the bath, proved unsatisfactory, the films being too thin. This can be overcome by coating a plate with an ordinary bromo-iodized collodion, which gives a good creamy film, sensitizing it as usual, and then washing. The plate should next be immersed in a solution of chlorine water, where the bromo-iodide will become converted into chloride. It should be well washed, plunged in the bath again, or a weak solution of silver flowed over it to restore sensitiveness, washed slightly, and used in the ordinary manner. A preservative applied will be of use in some cases.

Another application of this method may be useful. After a picture on a dry plate has been well developed by the alkaline method, and the reduced silver dissolved away with nitric acid, the plate may be treated with chlorine water, &c., as above, and the transparency, or reproduced (but reversed) negative, darkened up by light to any desired degree of intensity. One or two similar applications of the above may suggest themselves.

The rationale of the process is, that chlorine will displace bromine and iodide; similarly, an iodized plate may be converted into a bromized plate by immersion in bromine water.

Chlorine is produced by a mixture of one part by weight of common salt, one part of binoxide of manganese, and two parts of sulphuric acid. These are brought into a good-sized flask, and gently warmed; chlorine is evolved in this, and this is passed into water, through a common vent tube passing through a cork in the neck of the flask.

### ELIMINATING HYPOSULPHITE FROM PRINTS.

BY F. GREGSON.

As the use of acetate of lead for the removal of the hyposulphite from prints is now attracting some attention, a few further remarks on the subject may perhaps be acceptable.

Upwards of two years ago I treated some prints with acetate of lead. One of these prints was forwarded to the Photographic Society of London, with a print from the same negative, washed in the ordinary manner. The latter was then showing signs of a bleaching or fading action, while the print treated with acetate of lead was unchanged. I have a duplicate of this print; it is still unchanged.

The test to which these kind of prints was put by a skilful amateur photographer, as given in the PHOTOGRAPHIC NEWS, June 6th, 1873, proves their stability. He says, referring to this process:—

"Prints taken by me last autumn twelve months were placed in a stable window-sill—or, I should say, carelessly thrown there—and have remained there ever since, exposed to winter damp and cold, and to summer heat and drought. The window faces the south, and is by no means weather proof, and yet the whites of the prints are now as pure as when taken from the fixing bath, though marked here and there by fly-stains and dust."

Photographers who neglect to use a process which practically has answered so well are neglecting their best interests; and the emancipation from the old and cumbersome washing machines, celebrated for their tearing of large prints, is something also to be considered. These machines have much to do with the fading of prints in many instances—when not kept scrupulously clean—becoming contaminated with hypo from imperfect washing of the prints, in the first instance, when intrusted to careless assistants. I have the utmost confidence in the decomposition of the hyposulphite by chemical means as a preventive of the fading of prints.

Since writing the article in the Society's Journal, and reprinted in the PHOTOGRAPHIC NEWS, April 4th, 1873, I find rain water is not essential, as there stated. I am now using spring water, as rain water is not available. On adding the lead solution the water becomes like milk, from the carbonate of lead formed. A few drops of acetic acid are then added, until its transparency is again restored. The prints are then passed through this solution by two persons, keeping about six prints in the vessel at a time; one person continually but slowly immersing them one at a time, the other removing them singly into another water to which a few drops of acetic acid have also been added, to prevent the lead again being precipitated in the pores of the print as a carbonate. A few changes of water are then given, and the operation is finished. Care should be taken not to tone so deep when lead is used, as it exerts a strong toning action; and if the prints are fully toned, or left in the lead solution too long, they will have a disagreeable bluish or lavender tint, like an over-toned print.

In the year 1860 I tried the system of securing the permanency of proofs toned in the usual way, advocated by Mr. Charles Martel in the PHOTOGRAPHIC NEWS, July 20th of that year. Some of these prints I have now, and although no care has been taken of them until lately, they are now as perfect as when they left the last water. They are somewhat over-toned, the sulphuric acid employed exerting a strong toning action, which should have been allowed for. It is desirable that others who tried this process would also state how their prints are preserved. I think it might again be tried with every prospect of being successful.

It will be found that the most permanent prints are those that have been but a very moderate time in the water, provided the hyposulphite has been eliminated. Long soaking will fade a print before it leaves the water, no matter how carefully it has been washed.

### NEW PHOTOGRAPHIC SPECTROSCOPICAL OBSERVATIONS.

BY PROF. H. VOGEL.

I HAVE continued my experiments on the influence of colouring bodies on the sensitiveness of different photographic films. I have observed that not only pure bromide, but also pure iodide and chloride of silver are by far more sensitive

to the blue, green, yellow, and red rays than hitherto alleged.

If the slit of the spectroscope be opened to 0.25–0.3 millimetres, and if the exposure is long enough, the three bodies are, indeed, sensitive to nearly all the rays of the spectrum; the least to the extreme red rays, the most to indigo rays.

The presence of a well-known body (though colourless) changes in a most striking manner the sensibility to colours of the spectrum; nitrate of silver solution, for example, has this effect. Pure dry iodide of silver is but slightly sensitive to ultra-violet and violet rays, more for indigo and blue rays, very little for the others exposed. Iodide of silver under nitrate is more sensitive to ultra-violet, violet, and indigo rays than the dry iodide. The sensitiveness increases from violet to indigo, but near the line G of Fraunhofer it diminishes suddenly, and the other colours act very forcibly.

I mention here that the extension of the action of the spectrum is different at different times, even for the same body. Till now it was observed that the power of violet and indigo rays was greatly diminished with the altitude of the sun; but I observed, in oft-repeated experiments, that there is a variation in the actinic power of spectrum colours, independent of the altitude of the sun. Sometimes I got a spectrum impression on bromide of silver from ultra-violet to red; at other times I got only an impression of indigo, blue, green, and yellow, though the altitude of the sun was the same.

Chloride of silver exposed dry is not very sensitive, but exposed long enough it shows an action to the line B in red. Coloured with naphthalin red, chloride of silver gives a curious result: it becomes most sensitive for yellow rays, less for red and green, and the least for blue.

We have here nearly the same proportion in the actinic power as in the sensibility of our eyes. If it were possible to make chloride of silver more sensitive, the coloured salt would be the very body for taking coloured pictures.

Bromo-iodized plates exposed dry, or under silver solutions, show, also, a very remarkable difference: exposed dry, they show the most sensitiveness to blue and green rays, less for indigo rays, and very little sensitiveness for violet; exposed under nitrate of silver, the sensitiveness is very strong for ultra-violet and violet, increases till the limit between violet and indigo shows its most intense point near up the line G, and diminishes gradually to the limits of green and yellow.

### ON PHOTOGRAPHIC RECIPES AND PHOTOGRAPHIC RESULTS.

BY PROF. H. VOGEL.

FOR a long time past photographic journals have preached from the text that recipes alone are not in a position to yield beautiful pictures, but that a man also is necessary who knows how to use them; and that not only a good collodion, as may now be everywhere purchased, and such-like products, are required, but, before everything, a well-chosen pose, satisfactory lighting, the right exposure, and competent retouching of the negative. A successful picture can only be obtained in this way. And yet it often seems as if this good advice is thrown to the winds. Not long ago, one of those busy quacks who rely upon the gullibility of photographers made the tour of North Germany, giving himself out as a traveller of Mr. Dallmeyer, from London. The suspicious part about the man was, however, that he less offered lenses for sale than collodion recipes, enlarging processes, and goodness only knows what else. He did some very good business, and when at last it transpired that Dallmeyer had no traveller in that part of the world, the fellow disappeared. Perhaps he has turned up somewhere else, and is carrying on his trade as successfully as ever, for a man who speculates on the ignorance of others always does better than an honourable and fair dealer. I was, however, considerably astonished when I was told that this man had a method

for sale which saved plate cleaning, and the process was no other than that of albumenizing the glass, which has been frequently discussed for some years past. The price charged for the process was five thalers (fifteen shillings). The same knowledge any of the purchasers might have obtained from a handbook at half the cost. For a recipe for durable albumenized paper the brave fellow obtained three thalers (nine shillings). The same recipe may be found on page 6 of my alphabetical photographic handbook, which is sold for a couple of shillings. These are only some examples of the secret processes for sale. The worst cases are, however, not made known, for the dupe, as a rule, is not anxious to make public how he has been done. There are photographers who hold themselves to be too well informed to require posting up from a journal or handbook, and when such a one becomes the prey of a quack, all we can say is, it only serves him right. Others, again, take in a journal, and also purchase a manual; but these lie incut upon the table; they know nothing of their contents, and they do not expect that what they have to-day purchased for several thalers of a hawker, was given yesterday in the journal gratis. Such people may perhaps accept my advice to look, at any rate, at the index of the manual or journal in their possession, before they entertain the proposition to purchase what they have already in their hands in black and white. In the capitals, where societies exist, general conversation among the members is, fortunately, a great safeguard against such swindles. In Germany there are societies in but few towns—in Vienna, Berlin, Hamburg. In other places the tendency to form societies retrogrades instead of progresses, apparently; the Dresden Society, under the direction of the busy Dr. Krone, having been dissolved on the 7th November, because of the lack of interest shown by members.

Under such circumstances the provincial photographer does well to become a country member of one of the societies in the capital, as he then learns many things from its transactions which are useful to him in his business, and protect him from quackery.

It is singular how certain photographic novelties, which are scarcely noticed in the capitals, are made much of in the provinces. As an instance of this I may mention the so-called Denier effects. This description of picture was spoken of favourably in our city, tried, and again forgotten. In the provinces, however, it was different. Never in my life have I received so many letters respecting a process published in my journal as I have in reference to this matter. One wanted information; the other brought a new process; a third was ready to communicate a method, for a consideration, for making these Denier pictures. Denier, nothing but Denier, was the watchword, and it would be so still to-day, if the public had not behaved rather coldly towards this kind of portrait. In Berlin, at any rate, they made no sensation.

It was different, however, with the Rembrandt pictures. This effective style of portrait found many disciples. The late M. Grasshoff produced them in large numbers; but now they are scarcely to be seen in Berlin, although they are more popular than ever in the provinces. I receive from all quarters of the earth questions about the Rembrandts. Many have, indeed, asked me for a recipe for Rembrandt collodion, as if it were the collodion that was at the bottom of it all. The Rembrandt portrait is not a collodion, but a light effect, and only by properly arranging the lighting up of the model is the result to be secured. Such effects of illumination may be easily brought about in the studio, although it is a little difficult to describe the plan in words—at any rate, to those who have no eye for the light and shade gradations in nature. Those who possess such knowledge will divine of themselves how Rembrandt effects are brought about, and I would remark that they may be obtained in every possible manner. I will here explain the simplest of all plans,

which may be carried out without the aid of any complicated arrangement of blinds. The figure here appended

gives the outline of a studio: W is the glass end of the room, M the wall. The sitter takes up a position at P, and turns his face in the direction of the arrow indicated, so that it appears, from the apparatus A, in profile. A three-quarter profile, or half-face position, may be assumed, if desired. Behind the sitter is the background, h, of any suitable colour, while r is a very light reflecting screen covered with white paper. A mirror may be employed in lieu thereof, which must be so placed that its action in lighting up the shadows is distinctly visible. S is a small screen placed beside the lens to prevent the entrance of injurious rays, for without it the glaring light from the window W would shine into the camera.

Top-light has little to do with the effect. The apparatus A may, if desired, be placed more to the left or right of the dotted lines. The arrangement is somewhat modified according as the glass window is longer or shorter, and therefore it is necessary to make a preliminary experiment in a studio before proceeding to work. The duration of the exposure should not be too short.

### Correspondence.

#### ON THE INFLUENCE OF COLOURED BODIES ON THE ACTIVITY OF DIFFERENT RAYS.

DEAR SIR.—In the *British Journal*, March 6th, page 139, is published an interesting article of Mr. Carey Lea. Mr. Lea has repeated and continued my experiments on the actinic action of certain coloured and uncoloured bodies which have the capacity of making bromide of silver sensitive to such rays as the body in question absorbs optically.

In my researches I observed the connection between the chemical and optical absorption with the only apparatus suitable for such purpose, that is, the spectroscope. Mr. Carey Lea, in continuing my experiments, employed a more simple means. He took an artificial spectrum, made by strips of coloured glass, or glass coated with different varnishes coloured with aniline colour and other transparent bodies. Mr. Lea says:—"No coloured glass can be obtained that exactly represents the colour of a prismatic spectrum, but a sufficient approach can with ease be had."

This sentence contains an error, and a very important one. It is very easy to select a series of glass strips which seem to be similar to the colours of the prismatic spectrum, but if these coloured strips be examined with a spectroscope, it is easy to scrutinize that there is a very remarkable difference. For example, I have before me a violet glass. The light going through this violet glass contains not a trace of the violet rays of the spectrum. I have a blue-coloured glass which is transparent not only for blue, but also for the red rays of the spectrum. Through different specimens of yellow glass pass nearly all the rays of the spectrum. A varnish coloured with coralline permits sometimes all the yellow rays to pass if the reaction of the body is an acid one; but also a good deal of the indigo rays, whose chemical

action is the most powerful I know. Coralline of alkaline reaction absorbs the yellow rays, but transmits the red, green, and blue rays—the latter in a quantity whose chemical action is by far more intense than the chemical action of the red rays, which pass through the same body, and which seem to be to the naked eye the most powerful. Therefore it is not possible to make spectroscopic experiments with strips of coloured glass, or any other coloured body.

Take, for example, a strip of glass coloured red with rosaniline varnish, and expose under this strip a bromide collodion plate (coloured or not), and you will observe a strong impression; but it would be a great error to conclude from this fact that red rays act strongly on the exposed plate; for through this glass, covered with rosaniline, pass the blue rays as freely as the red ones; no one can determine whether the observed action is exercised by the one or by the other.

It is, for example also, a well-established fact that the indigo rays are the most actinic; but if an artificial instead of the true spectrum be employed, anybody could show that the activity of the indigo and blue rays and non-activity of the red and yellow rays is an error. Make, for example, an artificial spectrum, painted with indigo pigment, Naples yellow, and alizarine red, and take a picture with an ordinary bromo-iodized plate, and you will observe that the red colour of alizarine is the most actinic, and that the yellow is less powerful in its action, but by far more so than the indigo pigment.

These instances may be sufficient to show that it is not possible to make spectroscopical experiments with a so-called artificial spectrum of glass strips, and that Mr. Lea's experiments in this direction neither contradict nor confirm any of the facts I have observed with the true spectrum.

An explanation of the facts observed by Mr. Lea is only possible if the strips employed by him, and the pigment with which he has coloured his sensitive papers, are exactly analysed by the spectroscope.

PROF. H. VOGEL.

Berlin, 16th March, 1874.

#### ACETATE OF LEAD FOR ELIMINATING HYPO.

SIR,—Mr. Newton's proposition of freeing prints from hypo by means of a salt of lead, I am glad to see, is again being ventilated in this country and America. This is now the second winter that I have exposed prints so prepared to the tender mercies of a very unweather-tight stable window, and there they have lain under the full influence of a southern sun, and winter frost and damp, and there they have remained unnoticed till to-day (for I had forgotten all about them till the notices in this week's NEWS recalled them to my memory, for I have not been in my studio for months). As far as I can judge, they are unaltered. The whites are as pure and the tones as fresh as when first fixed. Others in my album retain all their pristine bloom.

I fancy, from the account in your American Correspondence, that the prints there mentioned must have been immersed too long or in too strong a solution of the lead salt, as from the description the tone was originally in a measure due to the acetate; and perhaps you may remember, in an article I ventured to send you last year, I particularly pointed out that immersion more or less distinctly affected the colour of the print.

As I have several large photographs on plain salt paper sensitized with ammonio-nitrate upwards of twenty years old, which show no sign of fading, possibly albumen must take to itself a great share of the blame. It is, wherever the fault lies, a disastrous result, that valuable photographs should be thus lost to all admirers of the art; and no one can look over volumes upon volumes of albums without lamenting the multitude of family and other mementos that have passed or are passing into "the sere and yellow."

While printing in pigments is likely for some time to come to be the exceptional, and not the normal, method of producing small (at all events C.D.V.) proofs, we cannot be too careful in eliminating, as far as practicable, that oppo-

rium of photography—prints that must fade; every new light, therefore, that can be thrown on the subject must be thankfully hailed as a step in advance.

Unfortunately, years are required to test the stability of a photograph. I admit I have faith in the lead salt, if judiciously used; but I shall not hesitate to abandon it if I find my hopes fallacious, either in my own practice or in the experience of others. One thing, however, is clear: the present system is the reverse of satisfactory.—I am, sir, your obedient servant,

R. M. S.

### Proceedings of Societies.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

The fourth popular meeting was held in Queen Street Hall on the evening of Wednesday, the 18th instant. The exhibition of a series of pictures of American scenery included some fine views in the Yosemite Valley, and some very clever instantaneous pictures of horses, cattle, and dogs.

Mr. DAVIES, who gave the descriptive lecture, began by saying that the first part of the exhibition, including the exceedingly beautiful instantaneous pictures, had been presented to the society by the Photographic Society of Philadelphia, through its secretary, Mr. Ellerslie Wallace, who, some of the members would remember, honoured them with a visit some time since. The pictures, as would be seen, were of a very high class, and he had no doubt that the members would see that they would require to "put their best foot forward," if they wished to keep abreast of their American cousins. Most of the Yosemite Valley and Niagara pictures had been kindly lent for exhibition by Mr. Walter Woodbury, and as they were printed by the process which bears his name, it would be seen that it was capable of giving very high-class transparencies.

The hall, as usual, was quite full, and the exhibition was in every respect a success, especially the portion relating to the Yosemite Valley, about which the lecturer gave much interesting information, for which he received a hearty vote of thanks.

#### PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The meeting of the Photographers' Benevolent Association, held at the Rooms of the Society of Arts on Thursday evening last, was, on account of the paucity of attendance, adjourned *sine die*.

The committee then proceeded to fill up the vacancies in the various offices by virtue of one of the rules, which provided for this contingency. The following gentlemen were duly elected, and, with two exceptions, have consented to serve:—As *Vice-Presidents*—Rev. F. F. Statham, M.A.; and J. H. Dallmeyer, Esq. *Trustees*—Col. Stuart Wortley; Capt. Abney, R.E.; W. England, Esq. *Auditors*—A. L. Henderson, Esq.; G. Taylor, Esq. *Board of Management*—Mr. G. Croughton (Chairman), Mr. Ganly (Deputy Chairman), Dr. R. J. Mann, Messrs. W. S. Bird, J. Skinner, Thos. Fall, W. T. Bovey, Ashuan, Jerjesen, Attwood, Corles, Wilson, Buchillot, Rheinlander, and Annand.

The committee have to acknowledge the receipt of £5 from Messrs. Mawson and Swan; £5 5s. from Messrs. Spencer, Sawyer, and Bird; £5 from Fred. York, Esq.; £3 from J. Skinner, Esq.; and £1 1s. from David Rees. From letters, &c., which the secretary receives, he can state that there is plenty of money waiting for the association as soon as the intending donors can see the assistants in photographic establishments take the matter up in a proper spirit.

### Talk in the Studio.

THE CONSERVATIVE CABINET.—Messrs. Dando and Co. favour us with a cabinet card containing a dozen medallion portraits neatly arranged, with the name attached to each, containing portraits of the most prominent members of the present Government. They are described as copied from a picture by Mr. William Lucas, but possess all the minute faithfulness of excellent photographs. The cabinet so photographed will form a welcome addition to many albums.

THE ATHENÆUM ON CARBON PRINTING.—It is not a little singular that the *Athenæum*—which, in times gone by, has often dwelt on lack of permanency as one of the chief drawbacks of photography—rarely fails to express a conviction that the carbon prints are inferior to silver prints in excellence. In a recent notice of some autotype enlargements it says:—"These are admirable productions in their way, although, like all 'autotypes' that we have seen, they lack the brilliancy and

clearness which are, in our opinion, the chief charms of photography. On the other hand, the great size of such works appears to us a positive disadvantage. No one wants such big things for his own house, and, however interesting they may be to photographers as *tours de force*, the general public are not likely to care for them. Of course we cannot criticize these things as works of art," &c. The question of the value of size must be determined by the purpose for which the pictures are required; but surely it illustrates a singularly unfortunate experience, or lack of appreciation, to declare that all autotypes lack brilliancy and clearness.

**PHOTOGRAPHING THE HEART'S PULSATIONS.**—Mystery is, no doubt, the soul of romance, hence romance is doomed, for so rapid are the strides now made by science in every direction, that there will shortly be no mystery left. No sooner has Dr. Broca invented an instrument for measuring the inside of the skull, thus literally "taking the measure" of any individual's mental capacity, than Dr. Ozanam, of Paris, originates a device by means of which "the beating of our own heart" may be photographed. The apparatus consists of a bag of india-rubber, to which a glass tube is fastened; this, being filled with quicksilver, is placed on the heart of the subject of the experiment, the movements of which are communicated to the quicksilver and indicated on the glass tube, while the results thus obtained are recorded by photographic appliances attached to the apparatus. It will greatly add to the interest of actions for breach of promise if, besides writing imprudent letters, fickle suitors take to proving the strength of their emotions by forwarding photographs of the state of their hearts, and the *pieces de conviction* at such trials consist, besides locks of hair, flowers, and other antiquated tokens of affection, of a correct register of the deceptive pulsations of those "foul, foolish, fluttering things."—*Echo*.

To Correspondents.

\*\* TO AGENTS AND ADVERTISERS.—Next Friday being Good Friday, the PHOTOGRAPHIC NEWS will be published on Thursday, April 2nd. Advertisers should send in their Announcements not later than Wednesday, the 1st.

A SUBSCRIBER SINCE 1866 will find many articles in the volumes he possesses on the subject of enamelling the surface of photographs, and these articles contain much fuller information than it is possible to give in this column, as he will readily understand that it is impossible to reprint full details for the aid of one reader, who can easily refer back. He will find a very clear but brief statement of the formula and operations on page 117 of our last YEAR-BOOK. He will require a plain collodion of the tough, horny kind, perfectly clean plate glass, a solution of gelatine, one ounce in eight of water. The plates of glass having been coated with the collodion, and suffered to dry, the prints are immersed in the warm solution of gelatine, placed upon the collodion, and pressed down with a squeegee. When set, they may be removed from the glass; but in this case they will lose much of their gloss on mounting. If the cards are attached to the prints whilst they are attached to the glass the gloss will be preserved. If it is preferred to remove them before mounting, the gloss may be preserved by using for mounting some substance which will soften the gelatine as little as possible, such as india-rubber paste, or a thick flour paste, or gelatine dissolved in spirit, sold by Marion and Co., and others. See the YEAR-BOOK article for further hints. There is no newer or more effective method. This is the method employed in France.

**SENSITIZER.**—There are two or three remedies for the troubles. If you examine the sheets whilst draining after sensitizing you will find the solution stands in drops upon the surface, instead of draining away in an even wave. The paper is probably exceedingly dry when sensitized. Place it for an hour or two before sensitizing in a somewhat damp place, to remove the horny dryness. Reducing the strength of the silver bath to about forty grains, and floating a little longer, will often prove a remedy; or, if you prefer to keep the bath stronger, blot off the superfluous silver solution with clean blotting-paper instead of allowing it to drain. This will certainly effect a cure.

**OPTICIS.**—We do not remember the precise address; but the name, with "Optician, Paris," will doubtless find him.

G. GILYETT.—We regret that we do not know one disengaged. The best plan will be to examine the advertisements in our pages, or to advertise.

G. THOMPSON.—The proper mode of removing the yellow spots will very much depend on their cause. If they are caused by iron, which many such yellowish brown spots are, the application of a solution of oxalic acid will remove them. Sponging gently with a solution of chloride of lime, and then rinsing, will remove much discolouration in an old engraving.

**PARALLAX.**—There is no advantage whatever in using an oval stop. Of course, looking at the head of a person with two eyes, you will see more of the sides than of the top and bottom; and if you use a large lens with full aperture you will, to some extent, have a similar result. Some photographers have recommended this plan as giving more effect of solidity and relief; but the disadvantages are greater than any advantage gained. In producing heads for enlargement we should not recommend you to place the camera at a shorter distance than twelve feet.

W. H. H.—The proper vessel in which silver solutions should be boiled is an evaporating dish of Berlin ware. Dealers in chemical apparatus, or most dealers in photographic material, will supply the article. A glass flask may frequently be used with safety by a person familiar with such manipulations. The thinness of the glass will check the risk of cracking from heat, but it increases the risk of mechanical injury. The kind of glass jar you used was probably one of the worst you could employ, being probably of common, badly annealed glass. Of course silver would be reduced by contact with the iron saucepan; but beyond the reduction of strength there will probably be no other injury. Make the solution slightly alkaline, sun, filter, and strengthen. Possibly an earthenware jar placed in a saucepan of water, resting upon a piece of wood, would permit boiling without risk. 2. We cannot judge much of the merits of the lens by the print enclosed. You will observe that it does not cover your cabinet portrait to the corners. The picture does not demand much comment; it is not bad, but is a little flat in the face, the result, apparently, of a somewhat dull diffused light.

**SUITABLE LIGHT.**—Both produce fine results when properly treated, but for certainty probably No. 1 is safest.

S. E.—We cannot assist you unless you give us details of the process you have employed. In doing so, please write as legibly and carefully as you can.

M. D. F.—Not at present. More information in due time. Several Correspondents in our next.

METEOROLOGICAL REPORT FOR FEBRUARY, 1874

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 35 feet above sea level.

1874 February Date.	Morning.	Noon.	Night.	Direction of Wind at 9 a.m.	
1	41°	41°	41°	S.	Fair and sunny.
2	41	43	41	S.W.	Foggy. Rain this evening.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO PHOTOGRAPHY AT THE HOME OFFICE—A NEW METHOD OF PRECIPITATING GOLD—DR. GAYER AND THE INDIAN FAMINE —THE CRAWSHAY PRIZES.

*Photography at the Home Office.*—Some time ago we mentioned the circumstance of the Home Office having adopted photography as a means of recording the results of explosions and other disastrous accidents in gunpowder factories and establishments where explosives are manufactured. According to statistics, it appears that in most powder mills an accident of some kind takes place with the utmost regularity about every ten years, and therefore the duty of securing photographs of such occurrences is one systematically occurring at certain definite intervals, for the number of manufacturers of explosives at present in this country is not only very large, but becoming more numerous every day. With gunpowder, gun-cotton, sawdust powder, white powder, fulminates, dynamites, rockets, composition pyrotechnic fires, and other abominations being made on all sides, peaceable citizens require some protection, and the Home Office, therefore, have recently appointed inspectors of explosive manufactures, in the same way as there are officers to control the working of mines, railways, &c. The duties of these are principally twofold: to make careful inspection, to see that due care is exercised, and the laws guiding the manufacture are complied with; and when an explosion or accident occurs, to report fully upon the cause, in order, if possible, to prevent such occurrences in future. It is in this latter respect that photography serves a most useful purpose, for a representation of the results of an explosion on a building, secured by the impartial camera, tells much to confirm or rebut evidence tendered by witnesses. A series of pictures representing various explosions are fitting documents for study, and guide the inspector in coming to a sound decision. The prints taken on each occasion serve, too, to illustrate the views brought forward by the officer in his report. One thing is found to be very necessary in securing such photographic results: they must be taken as soon after the accident as possible, else the freshly made fractures or cracks are apt to discolour, and the iron work become rusty by exposure to the atmosphere; moreover, ricketty portions of the walls and ceilings left standing often fall down afterwards if the interval between the catastrophe and the arrival of the photographer is prolonged for a day or two. For this reason it has been found necessary to have at hand a set of apparatus which can be used at a moment's notice, and which does not require extraordinary means for its conveyance about the country. The same consists of a camera to take twelve by ten pictures, dark slides to contain four dry plates, and focussing cloth, all of which fit into a leather case, or portmanteau, measuring seventeen inches by eleven. This, although rather a heavy affair for one man, can, at any rate, be carried by a photographer at a pinch, a broad sling strap that goes across the shoulders helping to support the weight. A leathern pocket, with the lens, slung as a field glass across the body, and a stand to be carried in the hand, complete the equipment. An assistant will be all the better, but he is not indispensable, and the apparatus might be set up, and the four plates taken in twenty minutes. If wet plates are to be employed, then the second man brings along with him a light dark tent and a few plates. It would be difficult to design a more compact and ready apparatus for taking plates of large size than that employed on the service by the Home Office.

*A New Method of Precipitating Gold.*—An experiment recently made by M. Paul Weisskopf concerning the precipitation of gold in a very fine state of division might, we think, be put to some application by photographers, either in toning silver prints, or intensifying the photographic

image upon a washed and fixed collodion plate. He finds that gold in a dilute solution may be precipitated by starch or milk sugar, aldehyde or alcohol, with addition of sodium hydrate, and with as little exposure to light as possible. The metal is thrown down in a very fine and soft powder, forming a deposit of a much more delicate nature than if sulphate of iron be used as a precipitant. The fact deserves the attention of photographers, and we are rather sanguine that some application of the experiment may be utilized by them. In any case, we deem it our duty to bring the matter to their notice.

*Dr. Gayer and the Indian Famine.*—It is always pleasant to meet an old friend, especially when you do so unexpectedly in an out-of-the-way part of the world. Dr. Gayer, whom our readers will remember as having communicated two papers of interest to the London Photographic Society last spring, the one on fixing albumenized prints, and the other describing a method of securing instantaneous pictures of live animalculæ in water, has come to the fore in Bengal to do what he can for the great Indian famine. He points out that, even in the event of your placing at the disposal of the starving large stores of rice, the provision of this article alone will not sustain life. Other foods—such as fish, pulse, peas, &c.—are absolutely necessary, and if these are not forthcoming, all the rice in the world will not mend matters. As we are aware, Dr. Gayer is an accomplished chemist, and, being a skilful physician to boot, his advice comes with twofold force. We trust he may be as successful as a physiological chemist as he has been in his photographic labours. It is doubly pleasing to meet with a photographer who is something more than a photographer, and in Dr. Gayer we certainly have such a man.

*The Crawshay Prizes.*—Our foreign brethren can put forward no excuse this year that the terms of the Crawshay prizes are not known abroad, for in the Continental and American periodicals the fact of that gentleman offering rewards for life-sized photographs is put prominently forward. Last year Dr. Van Mouckhoven complained, and with some reason, that no announcement of the important matter had been made to himself and friends through the medium of the Continental press, and stated that the competition was really confined to photographers in this country. Such an assertion can scarcely be repeated this year.

### ART PRINCIPLES FOR PHOTOGRAPHERS.\*

31. THE study of light and shade is one of the first things a portrait photographer should take up. By means of light and shade we obtain roundness, relief, breadth, distance, and other effects as they are in nature, and as they should be in our pictures.

32. To understand the laws that control light and shade, we must refer to that branch of knowledge which treats of the laws and properties of light and of vision, as performed by the eye, or what are generally understood as the laws of optics.

33. Self-luminous bodies discharge light, and non-luminous ones do not. For this reason we have so much difficulty in getting the effect we desire when persons dress in varied colours—light and dark—and, worse too, have them assorted in spots, so to speak, about their persons. There are self-luminous faces too; witness the greasy, shiny face, and the light-skinned and fair-haired, as well as non-luminous ones; witness the sallow, dry, and dark complexions. We should particularly remember this when lighting and shading a head.

34. All bodies, whether self-luminous or the reverse, discharge light of their own colour. Thus, red will discharge red light, even when illuminated by the sun, and that is why red hair, red complexions, and red drapery take dark.

\* Continued from page 477, last vol.

35. Again, light consists of separate or independent parts, called rays, which move in straight lines. When these rays fall upon any object, part of them are reflected, or part of them are absorbed by the object, if not transmitted through it. When the objects are bright, as a shiny face or silken drapery, a great part of the light is reflected. In other cases (we now speak of photographic portraiture) the light is more or less absorbed, and that is why we have shadows in our pictures.

36. You cannot have a better illustration of the principles of light and shade than a good round head. It is a study for an age, and if you learn to like the study, it will always give you fresh pleasure.

37. Pure white has no business in the photograph of a face, unless it be most delicately managed on the extreme high-lights. We want first the transparent shade, then the middle tints, and finally the extreme shades. This latter will always come directly opposite the focus of illumination.

38. The higher your light, or source of light, the more diffused will be the effect on the model, for the shadows will be shorter. The quantity of illumination should be carefully managed. Remember that in a photograph light is white, and where you direct light recklessly, you whitewash your model recklessly.

39. Touching the relief of figures, objects contrasted with a light background will appear much more detached than those placed against a dark one. Those parts which are the farthest from the light are the darkest, and will either eut hard upon the background, or appear to become a part of it. A graduated background should be used generally, so that the dark side of your model may fall upon a light ground, and *vice versa*. This arrangement serves to detach the figure, and at the same time contributes to harmony of effect.

40. Reflected lights will be more or less apparent in proportion as they are seen against a darker or brighter background, because of the force of contrast. Reflectors should be used judiciously so as to modify the shadows, but not to utterly destroy them, or to make the distant parts too light.

41. The exclusive power of light and shade is to give substance to form, place to figure, and to create space.

42. Shade is not obscurity, but is a gradation of light. The transition from light to shade should be imperceptible. For the gradation of light that produces the middle tints there are two causes: first, the objects recede from the light, and next from the spectator.

43. The lights and shades must be so distributed as to give force and strength to the picture when viewed as a whole. The lights should be collected and managed in such a manner that all will support and relieve one another. If they are multiplied, broken, subdivided, no relief will be obtained; but if the relative parts are harmonized, and so arranged as to give shade to light, and light to shade, they form a strong combination, and produce a powerful effect.

44. We have now considered the subjects of form, and light, and shade, the principles of art which specially come into play in the practice of photography. Any diligent student who has the taste may acquire further knowledge of them, if he will, in his daily practice. His success will depend upon his ability to finish what science has begun. We give you the formula. Now put your mind to it and work out the result. Taste will now come in and dictate; the judgment and skill will modify and improve, and your own spirit must guide the work of the hands. Now begins that ideal imitation for which your previous studies have prepared you.

45. We now come to the subject of expression—not so much the expression of the face, as the general expression or appearance of the whole picture—everything that gives

character to the work. The form, countenance, attitude, &c., must all be treated with reference to expression.

46. Expression is the highest attainment of art, and is both definite and general. It belongs to every part of the work, and stamps its value. It completes the work, and demands the exercise of your greatest abilities and acquirements. First the outlines, then the light and shade, take their part in adding to the expression of your picture, and give beauty to the character of it, but they cannot redeem its defects. You must also consider proportion, which is as great and essential to truth of character as to beauty of form.

47. Fuseli remarks that "expression principally consists in representing the human body and all its parts in action suitable to it." No two faces are alike in form, and the artist who would excel in expression must understand the physical construction that belongs to the temperament of his subjects. You would not pose a large man in some fantastic, dandy position. Neither should you allow a slender, graceful person to stand stiff and erect, without a bit of grace or ease—expression—in the pose.

48. Learn to study people as you meet them, in or out of your studio. When Leonardo da Vinci chanced to see a man with an expression of character that he wished to make use of in his work, he would follow him and study him until he was able to paint his face. So should you study men and women as you see them, and when you observe a good pose, or anything to suggest one, commit it to memory, to be used as a sketch for future work.

49. Much of the expression of a picture is due to the proper arrangement of the drapery—upon the number, size, and disposition of the folds, for on these depend the grace and beauty of the figure. Large folds, few in number, are better than many small ones, for the effect is less spotty. If the quality of the drapery requires small folds, they should be so distributed as to form a mass equal to one principal fold. Then they must be fully relieved by light and shade, or they lose their effect.

50. Arrange the drapery so as to fit the figure, and not conceal it; vary the size of the folds. Let them appear principally where they are held on by the arms and hands of the figure, and the rest be left to fall with ease and simplicity. Arrange the folds to harmonize with the position of the figure, as with its proportion. Great spirit and life may often be given to a figure by the direct opposition of lights and shades in the close deep folds, and grace, breadth, and harmony by those more ample and extended. Study all these things.

(To be continued.)

#### THE INTERNATIONAL EXHIBITION OF 1874.

IN Lieut. Cole's excellent paper before the Society of Arts he gives an interesting summary of the scheme of the exhibition for the present year.

"Commencing with the Fine Art division, there will be oil paintings, sculpture, and applied art from foreign countries and the United Kingdom, and the picture galleries will be well filled. Space will be reserved for a collection of works of applied fine arts, and it is felt that this will meet the demand for a 'Royal Academy'—so to speak—for Industrial Art. There will be a special exhibition of sketches, subjects from the Queen's dominions over the world, executed by officers of the Army and Navy; and there will be collections of architectural designs, photographs, and engravings. Among the designs, the committee recommended the formation of a special collection of these for scholastic buildings. As last year, and in revival of the example set by this society, when collections were made of the works of Mulready (in 1848) and Etty (in 1849), there will be a collection of the works of deceased eminent British artists, and the owners of the works of

some of the following artists have contributed to the exhibition:—

PAINTERS IN OIL.			
		Died.	Died.
J. Constable, R.A. ....	1837	David Roberts, R.A. ....	1864
Augustus Egg, R.A. ....	1863	David Wilkie, R.A. ....	1841
PAINTERS IN WATER COLOURS.			
		Died.	Died.
J. Coney .....	1833	A. Pagia . . . . .	1832
J. S. Cotman .. . . .	1842	J. M. W. Turner, R.A.	
F. Mackenzie .....	1854	(Architecture only)	1851
S. Prout .....	1852	C. Wild .....	1835

“The collections are intended to be educational, and for the purpose of illustrating the careers of well-known British artists.

- “In the industrial division for this year, the classes are:—  
 Lace (hand and machine made).  
 Civil engineering, architectural and building contrivances.  
 Heating, by all methods.  
 Leather, including saddlery and harness.  
 Bookbinding.  
 Foreign wines, in the vaults of the Royal Albert Hall.

“As regards the prospects of each of these, there will be lace from France, Belgium, Austria, Russia, &c.; there will be machine lace, and a machine at work, contributed by the Nottingham Chamber of Commerce; lace from Bedford, Buckingham, Ireland, &c., and workwomen to show how it is made on the pillow. There will also be a very interesting collection of ancient lace, formed under the direction and advice of a special committee of ladies, the Princess Christian being the president.

“In civil engineering and building, France will contribute models of new buildings in Paris; and there will be a large show of structural buildings, models, and designs. Several sewage processes will be shown in operation, as also methods for concrete buildings. In heating, there will be a good collection of all kinds of stoves entered to compete for the prizes of this society, and tested in houses constructed for the purpose in the exhibition grounds. In leather, there will be an abundance of machinery in operation, and a good show of finished goods. In bookbinding, there will be illustrations of machine processes by steam and hand; a show of modern works in cloth, paper, and leather; also a collection of old bindings.

“The exhibition of foreign wines in the cellars of the Albert Hall promises to be one of the striking features of the exhibition. A committee of gentlemen has laboured hard to bring together every conceivable variety of honest wine from all parts of the world, and the public, after being charged sixpence a-head, may enter the well-lit cellars, and there, as in the sampling-rooms of wine merchants, may obtain wine to taste; the agent of the exhibitor being permitted to make a charge at discretion. There will be wines from France, Spain, Portugal, Italy, Hungary, Austria, Greece, Australia, &c.; and, as far as possible, the wines of each country will be kept in separate cellars.

“The third division of the exhibition—*i.e.*, scientific inventions—will be well represented; Gramme’s electro-magnetic light, and a system of casting under pressure, being among the most notable of the exhibits.

“In concluding, I would again remind you that if you do not find the exhibition of this year an attractive *coup d’œil* of trophies, you will find some branches of industry made intelligible, and you will be able to study such a picture of the state of art in Europe as cannot this year be examined in any other spot in the world.”

CRIMINAL PHOTOGRAPHY.\*

WE have not yet come to an end of the additions made to the useful applications of photography. Nay, we seem to be still only on the threshold. Portraits—somewhat unmeaningly called *cartes-de-visite*—small enough to be in-

\* All the Year Round.

serted in an album, continue to be the main production of the art; but the variety in other directions is becoming amazingly large. Landscape, sea, and sky have been brought within the range of the camera, with surprising results; geological stratification and mineral structure are copied with a fidelity never before possible; leaves, buds, tendrils, bark, and roots have been made to tell their secrets to the collodionised plate; wings, furs, plumage, skin, hair, are in like manner revealed as to their surface structure. Medical men take photographs of diseased organs and tissues as among the best modes of comparing one disease with another. Archæologists photograph ancient marbles and inscriptions, ancient bronzes and coins. Ethnologists fix by a similar agency the characteristic portraiture of nations and tribes. Astronomers, by the aid of the camera, have largely increased the knowledge which the telescope and the spectroscope had given them of the sun, moon, and other heavenly bodies; and are preparing to use the same valuable auxiliary in watching the transit of Venus. Civil engineers take photographs of broken bridges and embankments, and mechanical engineers of broken boilers and locomotives, that they may have before them a permanent record of each disaster, so far as concerns the actual appearance of the fragments. And now justice steps in to claim her share in the service which photography renders to mankind. She asserts that when a rogue has become well-nigh incorrigible, it is right that the officers of the law should have an eye upon him, and a clue whereby they may know him again when he again transgresses.

During a few years past, a custom has occasionally been adopted of taking photographs of criminals in prison—not, of course, to gratify the criminals themselves, but to obtain permanent means of knowing them again. This was generally decided on by individual magistrates, or jail-governors, who foresaw the value of the system; and evidence has been afforded that they were not wrong in anticipating useful results. In one instance, two men stole some sheep in the north of England, drove them south, and added to the number as they went on. They sold them in London, and got off with the proceeds; but the detectives ferreted them out, and lodged them in Shrewsbury Jail. As a means of obtaining evidence, the police required that the thieves should be identified in the districts through which they had passed. A photographer took their likenesses; copies of these were sent to the several districts; and the clue thus obtained led to the conviction of the offenders. In another instance, where a murder had been committed at Durham, a photograph of a suspected man was sent by the police to the house of one John Owen, a tailor, in a distant part of England. It was immediately recognized by Owen’s daughters, one of whom exclaimed, in tears, “Oh, it’s our Jack; there is no doubt about it now;” and Owen himself also acknowledged that the photograph was a portrait of his son, against whom suspicion had already been aroused, and who proved to be the murderer.

When it was proposed, about three years ago, to establish this as a regular system, objections were raised to it by some portion of the press. It was urged that there are generally seven or eight thousand convicts in the various convict prisons, beside prisoners in other jails; that to take and keep photographs of them all would produce a criminal album of a most portentous bulk; that it would be unfair to photograph a man against his will, and thus render him an object of suspicion for the rest of his life; and that an ingenious rogue might so effectually distort his features, as to render identification difficult, if not impossible. And it was added: “Of what use will the photographs be? Criminal faces are almost all of one type. There is but little individuality about them; and the various photographic portraits, which will compose the new criminal gallery, will have so unusually strong a family likeness as to be of little or no practical value in establishing the identity of a prisoner.” These objections were without difficulty removed. As to the number of photographs, this might be lessened to

any degree if the results were not found adequate to the expense. As to the unfairness of photographing a man without his own consent, this objection falls to the ground; the photographs are for the police authorities, not for the public; and they are portraits of wrong-doers, concerning whose future proceedings society has a right to be placed on its guard. And as to the family likeness among rogues, every day's experience disproves this; some of the most benevolent looking hypocrites are to be found among our criminals.

There is more cogency in the objection that a criminal might so twist about his face as to render a photograph wanting in real identity. The authorities have experienced this, and have adopted means for frustrating the cunning. On one occasion, at Shrewsbury, where a convict knew that he was to be photographed, he made such horrible contortions as to spoil the plate, and then a second. At a third attempt the photographer only pretended to be at work; he had either no lens in his camera, or no collodionized plate behind the lens. After a few moments, he shut down the apparatus with an expression of annoyance, and went into the dark chamber as if to develop a negative. The convict, thrown off his guard, resumed his ordinary shape of features; and at that moment a second photographer, quietly placed behind a screen, did the work effectually through a small opening. In other instances, by previous concert with the prison warders, the photographs have been taken in the labour-yard, at the instant when a prisoner was standing before a small opening in the wall. In most cases, however, a threat of shortening the rations, or increasing the labour, has been effectual in inducing the rogues to leave their features in their natural form.

Three years ago, the Secretary of State for the Home Department, in the exercise of power intrusted to him by Parliament, issued an order to the magistrates to furnish the Commissioners of Police with photographs of all offenders in county prisons, whose offences brought them within the statutory meaning of the Habitual Criminal's Act; thereby giving systematic effect to a plan which had before been only partially adopted. The Chief Commissioner of Police, reporting on the subject about a year afterwards, stated that the order had not been so well carried out as had been expected, but that the full benefit of the system might eventually be looked for. "It is confidently expected that a more general use of photography, the exercise of greater care in observing and noting any peculiarities in the personal appearance of prisoners respecting whose antecedents information is sought, and the cordial co-operation of the police and prison authorities of the kingdom with the Central Register Office, will lead to the frequent identification of old offenders. Many prisoners have been identified by means of their photographs, and former convictions proved. Occasional use has been made of photography in special cases with good results; and the system recently established of visiting prisons has given the detective officers a good knowledge of thieves."

Two years ago a new Act was passed to give more definite effect to the Home Secretary's order. Registers of convictions are to be kept in a prescribed form at central offices in London, Edinburgh, and Dublin. The governor, or chief officer of every jail, is to make returns of the persons convicted of crime who come into his custody. Regulations are to be made for photographing all prisoners convicted of crime, confined in any prisons; and refusal to obey any regulation made in this matter is to be deemed an offence against prison discipline. The expenses of keeping the register are to be paid by the Treasury; but the outlay for photographing the convicts is to be deemed a part of the regular expenses of each prison or jail.

An interesting parliamentary paper has recently been issued, giving an account of the results of this system, during the short time that it has been in force in a regular way. Down to the end of 1872, more than thirty thousand photographs of criminals had been received by the Commissioners of Metropolitan Police, and deposited in

the Habitual Criminals' Office, from the governors of county and borough jails and convict prisons. This was in little more than twelve months. Going back another year, to the date when the Home Secretary's order was issued, the total number amounted to forty-three thousand, forwarded from a hundred and two prisons in England, and thirteen in Wales (the experiences of Scotland and Ireland are not reported in this document). As we know pretty well the cost of photographic album portraits, done in the usual way, we may have a pardonable curiosity to learn the cost of those relating to criminals. This information the parliamentary paper gives us; for it appears that the forty-three thousand photographs have cost three thousand pounds—about one shilling and fourpence each. The rogues are certainly not worthy of this sixteenpence apiece; but then it is bestowed, not for their benefit, but as a safeguard in the hands of justice.

The House of Commons, in ordering the returns, to which the paper relates, requested to be informed in how many cases the photographs had led to the identification and conviction of offenders. Many of the governors of county and borough prisons were unable to furnish information on this point. Some said "not known," some "no record kept," some "not recorded," some "cannot ascertain," many of them plainly said "none," while the rest furnished instances of successful application. The Bedford County Prison reported: "Of the hundred and five county prisoners, twenty have been detected through the aid of photography. Cornwall said: "In many cases information received from the Habitual Criminals' Register—by photographs sent on jail forms for recognition—has led to the identification of old offenders. Dorset could tell of "six cases known;" while Herefordshire reported that "three who have been in custody here were recognised by the police elsewhere through their photographs." The authorities at the Holloway City Prison had no means of knowing accurately the number of cases in which photographs had led to the identification and detection of criminals; but, "at any rate, they can say that about thirty of the number have since come under their observation, and have been re-dealt with for fresh offences, in most instances receiving a sentence of penal servitude." At Leicester Borough Prison, three male prisoners had been detected, before trial, by means of portraits sent round to different counties, of having been previously convicted of felony. At Newgate many prisoners had been identified by means of photographs received from the Government convict prisons.

Some of the prisons sent memoranda of the cost that had been incurred in bringing the photographing arrangements into working order. Monmouthshire told of twenty-five pounds spent upon a studio; while at the Liverpool Borough Prison an expense of ninety-five pounds had been incurred for a photographing room, and sixty pounds per annum for the services of a photographer. Here and there the governor of the prison is a tolerably efficient amateur in this art, and has managed the matter without any cost to the county or borough. So far as we can judge from the returns, only one copy of each photograph is usually taken, but in some instances there are evidently more. Thus of two hundred and twenty-eight photographs sent to the Habitual Criminals' Office from Leicester, twenty-two were duplicate copies. Of five hundred and eighty-two taken at the City Prison, Holloway, two hundred and twenty-four were furnished to the Registry, three hundred and twenty-eight to the City police, and thirty to the magistrate. In all probability there were several triplicates in this instance. The greatest number sent by any one prison to the Criminal Registry were from Newgate, nearly four thousand eight hundred; next to this was Coldbath Fields Prisons, about two thousand eight hundred; Liverpool Borough Prison came next, with two thousand eight hundred; and Westminster County Prison, with two thousand three hundred. From these high numbers we come down to Lincoln County Prison, which sent just one

photograph, and only one, for which an outlay of three shillings and sixpence is recorded. It might be supposed that Newgate, with its large brigade of photographs transmitted to Scotland Yard, would be able to point to a goodly number of instances in which these have led to the detection of criminals; but there is one reason why the authorities at Newgate have no means of testing this matter: "The prisoners convicted here are, after trial, removed to various prisons to undergo their respective sentences;" and Newgate sees nothing more of them unless a subsequent conviction, for other crimes, happens to take place within the district of which this prison is the headquarters.

It is not alone in this country that photography has been brought into requisition as an aid to the administration of justice, nor, indeed, was it with us that the system first began. Every principal police station in the United States of America has for some years past had its "Rogues' Gallery"—a collection of portraits of offenders whose future proceedings require watching, and whose personal identity might clear up some otherwise insoluble puzzlement. It may perchance be only a joke, but the American thieves are still, in self-defence, to have established a "Detectives' Gallery"—portraits of such police officers as it might be worth while to avoid. Cunning rogues are more likely, we imagine, to photograph such lineaments on their brains or memories than on collodionized plates of glass.

### SUCCESS IN BUSINESS.

BY PROF. VOGEL.\*

WHEN MM. Loescher and Petsch, the well-known Berlin photographers, left their old studio some four years ago—where they had carried on a prosperous business for some time, and secured a goodly share of honour and money—and proceeded to move into more commodious quarters, built upon improved principles, a worthy old glazier was heard to remark: "What a fool I have been to be sure! I might have had that old studio if I had liked. It was offered to me before ever Loescher and Petsch were thought of. If I had only taken it I should be a made man now." "Are you a photographer, then?" I asked him. "Oh dear no," he replied; "but you can easily learn to be one in six weeks, you know, and the money required to buy such good machines as those of Loescher and Petsch I could easily have borrowed from my brother-in-law."

The worthy old glazier compared the success of Loescher and Petsch to that of an organ grinder who discoursed music by turning a handle. The refreshing greenness of this man may, perhaps, be pardoned; but it is pitiable to see similar ideas participated in by those in higher stations of life. "I see that both your machine and yourself work well," wrote once a well-known authoress to a photographer in Berlin. It would be pretty much the same as if a musical critic were to say, in discussing a concert by the renowned Liszt: "That piano of Broadwood's and Liszt played most exquisitely the other night."

This disparaging estimate of photographic success has very naturally an injurious influence upon the social position of the photographer, and that alone is bad enough, in all conscience; but worse still is it when this false view of photographic success or failure is entertained by assistants in the studio. It very often happens that a well-known artistic photographer engages for his work a draughtsman of moderate intelligence, whom he instructs in the matter of negative retouching. The assistant, after some weeks' practice, actually succeeds so well that he can work quite passably, provided that his principal looks after him pretty frequently, and points out his errors continually. In this way matters go on for a year quite

smoothly. Suddenly, however, an idea occurs to the retoucher while pursuing his lonely task, with his mind left free for thinking. He flatters himself he is the principal man in the business, and tells himself, with pride, that without his work the renowned and well-paid-for pictures which his chief sells would be of no value at all. The deduction which follows is but natural, viz., that the fine sums of money which his principal earns through his aid, secured by a paltry weekly stipend, could with but little trouble be transferred to himself. A relation supports him in the idea, money is obtained from somewhere, savings are added to the sum, and an atelier is rented. The furnishing of this swallows up all the funds at disposal, for, in full reliance upon his skill, he takes a studio in one of the finest quarters of the town. A *clientelle* is actually established through the recommendations of friends.

Then the young man begins to feel that he is scarcely so experienced as his principal as regards his relations with the public and the posing of sitters. He does not possess a knowledge of the right way of going to work, nor how to bring out the strong points, and hide the weak ones, of his models. He hopes, however, to compensate for all this in his retouching of the negative. The negatives are worked upon until the features are as smooth as those of wax dolls. With all these efforts, however, the result is far behind that obtained by his late principal; the reason being, that not only has the new photographer no taste, but he lacks, moreover, technical knowledge and experience. He was doubtless in a position, when supervised by others, to undertake a duty, and carry it out successfully; but he is not competent to conduct a business by himself. His enterprise does not succeed, the invested capital is lost, and at the end of six months the speculator has become a wiser man, and is once more retoucher to his former chief. I have here sketched a picture from life, and have only omitted the name of the narrator of the story. It is by no means a solitary instance which I know of.

Very apt indeed are assistants in large studios to over-estimate the service they render, and the things of which they are capable; they imagine they can do by themselves that which their principal carries out with their aid, frequently only discovering their error when it is too late. I do not mean to warn them once for all that they must not presume to become independent. Those who do not feel competent to serve the upper ten thousand may be able to give more humble citizens what they require, and those who hesitate to undertake the direction of a magnificent studio in the metropolis may be content with the modest proportions of an *atelier* in the provinces. I have myself had pupils who were deficient in the matter of taste, and yet they make a very fair income, derived from a public which had less, and estimated highly the pictures supplied them. I also remember the circumstance of a photographer in a little provincial town doing a good business, whose comb and feather suddenly began to swell and puff out. He was the first photographer in the town of Mudborough, and, as a matter of course, the Mudburghers went mad over his pictures. So at last he became vain, and believing himself to be born for a higher state of things resolved to extend his sphere by removing to the metropolis. He was blind enough not to see that his pictures were far behind those produced in the capital; he spent an enormous sum in the construction of a magnificent studio, and then came to a brilliant and speedy end.

Those who desire to be independent should first of all test their powers very accurately, and choose their sphere of action accordingly; and, above all, they must not put their expectations too high. In order to attain to genuine success in photographic portraiture a multitude of various qualities combined are necessary, such as artistic knowledge, natural aptitude, technical skill, presence of mind, energy, business knowledge, and unflinching industry.

## NEW MODE OF REPRODUCING NEGATIVES.

If photographers perfectly understood their own interests, the multiplication of negatives would be a familiar practice, and the best and simplest means of effecting such multiplication a subject of the most vital interest. No photographer should print from a valuable negative until he has secured duplicates of it as nearly as possible equal to the original. Of all the works issued from the press illustrated with woodcuts, there is scarcely one, perhaps, in the present day in which the original wood-block is employed to print from, a reproduction in electrotype being universally obtained and printed from the original engraving on wood being retained for making further electros; and it is only where a very choice edition is required on the one hand, or where the matter is very unimportant on the other, that the original wood-block is used in the ordinary printing operations. The same conditions ought to exist with the photographer. His ordinary every-day negatives, from which a dozen or two copies may be required, and no more, would probably not be worth the trouble of reproducing; but in all cases where a fine negative of a valuable subject has been obtained, whether in portraiture, landscape, or pictorial study, the first step should be to secure good duplicates—to secure safety in the first place, and aid in rapid printing on the other. Already some very excellent modes of reproducing negatives exist; but we are about to refer to another which seems to possess some advantages over all which have been described.

An article in our last, by Herr Obernetter, describes a process worthy of the most careful attention; and since it may easily be overlooked, as referring to something with which many photographers are not very familiar, we again call attention to the method described, and its advantages. The method Herr Obernetter has worked out is practically the same as Joubert's enamel process, and, besides excellence of result, it possesses the advantage of extreme simplicity. Unlike most other methods of reproducing negatives, it is a direct process; the negative is produced at once from a negative without the intermediate aid of a transparency. It gives the operator a singular amount of control in modifying the character of the reproduced negative if he wish so to modify it, not merely in making it more or less soft or vigorous, but in varying the distribution of light and shade upon the background and other flat portions of the picture. It is not simply a suggestion, but a process which has been thoroughly worked out, Herr Obernetter having reproduced by the plan in question no less than two thousand negatives during the last three years, many of them of very large size, some of them nearly

thirty inches long; and he described the results as so perfect that the eye of the most practised photographer is frequently unable to distinguish between the original negative and the duplicate. The chief difficulty which will seem to arise will consist in the unfamiliarity of the operations and materials to many photographers. Those who have tried the various powder carbon processes and powder enamel processes will probably find no difficulty at all; and photographers generally will find no difficulty which patience and experience will not readily overcome.

The method is worked in the following manner: a plate of glass—patent plate with a clean perfect surface—is taken to the dark room, and coated with a syrup-like solution prepared as follows:—

Dextrine ... ..	1 drachm
Ordinary white sugar ... ..	1½ "
Bichromate of ammonia... ..	½ "
Water ... ..	3 ounces
Glycerine . . . . .	2 to 8 drops

This solution is filtered, and may be kept ready for use without deterioration for a few days. The plate, being coated, must be placed in a horizontal position in a drying closet, or some suitable place free from dust, to be dried at a temperature of from 120° to 160° Fahrenheit. It is then placed under the negative at once in a suitable printing-frame, and exposed to diffused daylight from ten to fifteen minutes, according to the density of the negative. This exposure will produce a visible image, brown upon the yellow film. It is now placed again in the drying closet, and allowed to gain a temperature just a little higher than that of the operating room. It is then removed to the dark room again, and laid upon a piece of white paper, which permits the progress of further operations to be seen satisfactorily. The image already formed upon the sensitive surface is now to be brought out and intensified to the required extent. To make the matter clear to those who are unfamiliar with the operations, we should explain that the film of dextrine and sugar is of a sticky or adhesive nature. Where light acts upon it through the negative, it becomes hardened, and loses this sticky character; where it is protected from the action of light by the dense portions of the negative it retains its sticky character, and retains or loses the sticky character in the precise ratio of the action of light through the various gradations of the negative. In producing enameled a transparency is used instead of a negative, and a ceramic powder is applied; in producing carbon prints a suitable pigment in powder is applied. But in reproducing negatives, a negative, of course, and not a transparency, is employed, and finely powdered graphite, or blacklead, is used. This is applied with a large camel's hair brush, gently spreading the powder all over the surface, to which it adheres in due gradation. And it is at this stage of the operations that any modification in the character of the negative may be secured. Assuming that a plain even tint prevails in the background of the negative, this may be modified, and varied degrees of light and shade secured. This is effected by applying the powder more heavily or more lightly, as may be desired. Breathing on the surface will increase its adhesive quality, and permit more powder to be heaped upon it; and, by applying the powder freely or sparingly, considerable variety of effect may be produced, and errors of exposure may also be modified by similar treatment. When the desired result is obtained, the superfluous powder is gently dusted away, and the film is coated with plain collodion of strong body and tough character. Equal parts of ether and alcohol, and about ten grains per ounce of pyroxyline, have been found suitable by Herr Obernetter. When this is well set, or in some cases when it is dry, the edge is cut round with a sharp knife, and the plate is placed in water. In a few minutes the film leaves the glass, and is turned over by the aid of a camel's hair pencil, and lifted out of the water on the sheet of glass, and is spread by gentle manipulation evenly on

the glass by means of the camel's hair pencil, and is then coated with a solution of gum arabic, ten grains in an ounce of water, and allowed to dry spontaneously, and may be varnished in the ordinary manner.

Some other details may be found in Herr Obernetter's article in our last. We have confined ourselves to briefly re-stating the general details as simply as possible, in order to refer to points of manipulation with which our experience in the powder process had rendered us familiar. The process appears to be eminently promising: it is certainly easy, and whilst it appears to be the shortest mode of reproducing negatives which has been proposed, it certainly gives the operator more control over the character of the results than any process we know of.

#### A NEW ENCAUSTIC PASTE.

M. CLEMENT SANS describes in the *Bulletin* of the French Society a new encaustic paste, said to possess many valuable qualities. He refers to the formula of an encaustic paste by Herr Grune, which we first published a few years ago. It consisted of Marseilles soap and white wax. M. Clement Sans says:—

"This composition spreads with great facility, and yields a good polish; it possesses, however, the inconvenience of scratching the albumen film, and has, moreover, a strong odour, which after a time becomes quite insupportable.

"I have modified this encaustic paste, and as it is now composed, no fear need be entertained of the surface of the print being damaged. The odour is, moreover, very agreeable, and it gives a more brilliant polish. Here is its composition; viz:—

Gum arabic, powdered ... ..	2 parts
Sugar candy, powdered... ..	5 "
Transparent glycerine soap, finely rasped	10 "
Water ... ..	quant. suff.

"The water is put in to moisten the soap and to dissolve the other ingredients. Afterwards there are added ten parts of white wax finely scraped.

"The paste is heated upon a sand bath until it reaches the boiling point, care being taken to stir the mixture continually, to prevent its burning. It should be contained in an earthen vessel, large enough to hold five times the quantity. A brown glazed coffee pot will answer the purpose very well. After boiling for a short time and being well stirred, it is poured into any suitable receptacle to cool. When cold, the encaustic paste should have the consistency of pomade. It is applied to photographic prints with a rag or tuft of cotton wool, in exactly the same way as other compositions of like nature."

#### MEASURING RAPID EXPOSURES.

AN instrument has been invented by MM. P. Champion and H. Pellit for the purpose of measuring or estimating the duration of exposures too rapid for ordinary counting. The instrument, described in the *Bulletin* of the French Society, is composed of two distinct parts: 1, the contact apparatus upon the lens; 2, the registering apparatus.

The contact apparatus is formed of a lens cap working by the aid of a lever. Opposite to this lever, a little metallic appendage upon the cap completes the electric circuit. The electric current does not pass so long as the sensitive plate is sheltered from the light, but as soon as the cap is removed the electric circuit is completed. It remains, therefore, to register this action of the cap, which is done by the second portion of the apparatus, composed of a clock-work pendulum movement, the rapidity of which may be varied according to circumstances. This mechanical arrangement sets in action a metal drum, the axis of which is in communication with the negative pole of a battery.

A peg fixed upon the wooden bar which supports the

apparatus carries at its extremity a loose iron wire, the point of which rests upon the drum, whose rapidity of revolution has previously been determined.

The drum, or disk, may have a diameter of eight centimetres, and be set going at a speed of half a revolution per second, or at the rate of twelve centimetres, or one hundred and twenty millimetres, in that period. Upon the drum is placed a band of paper impregnated with a solution of ferrocyanide of potassium and nitrate of ammonium, the surface being always kept very moist.

The point of the iron wire is in connection with the positive terminal of the battery by means of a separate conducting wire in front of the cap.

Let us now suppose the apparatus at work, and a sensitive plate in the camera with the lens fitted as above. On removing the cap by the aid of the lever, to allow the light to act through the lens, we shall complete the electric circuit, and the iron point will trace a blue line (in Prussian blue) upon the drum, the mark being prolonged as long as the lens is uncovered. As soon, however, as the cap is re-adjusted, the electric current will cease to pass.

In this way we shall produce a line which may be measured as soon as the paper is removed from the drum. If we suppose that the apparatus was destined to give a rapid exposure, and the drum was revolving at the rate of once in three seconds—or, in other words, at the rate of eight centimetres in a second of time—at the time of the experiment; and if we obtain a blue line, traced during the exposure, measuring six centimetres in length, then we know that we have allowed the light to act upon the plate for the space of six-eighths or three-fourths of a second. If the exposure had been less rapid, and a line of twelve centimetres had been registered, then we should know that the time given to secure the negative was precisely a second and a-half.

In this way it is possible to estimate with the greatest precision the duration of an exposure of the plate in a camera, and to arrive at results quite independent of the operator.

[As we pointed out last week in the account of Lord Lindsay's expedition, that nobleman has already secured an electric recording apparatus, no doubt similar in principle to that here described, for his observations of the transit of Venus.—Ed. P.N.]

#### ON THE ELIMINATION OF HYPOSULPHITE FROM NEGATIVES.

BY HENRY GREGSON.

MANY of your readers have, I presume, been exceedingly annoyed by the loss of valuable negatives by crystallization, that from haste or other causes have had insufficient washing, after fixing with hyposulphite of soda, both before and after varnishing. Sometimes it is years before this is perceived. It generally first shows itself in the thick edge of the film, where a decomposition of the varnish shows the presence of the enemy. Sometimes it appears in small points over the negative, spoiling every print, for which the paper is often blamed, and which re-varnishing will not always remove.

I have for some years used the following method of decomposing the hypo in the film, and have not lost a negative from crystallization since. My immunity from the cracking of varnished films of late I partly attribute to this method. Make a stock solution—

Iodine ... ..	30 grains
Iodide potassium ... ..	40 "
Water ... ..	5 ounces

For use, to one part of this add four parts water. Wash the negative as usual, and pour on this solution similar to developing, when, if hypo is present, a milky precipitate is produced, and, on returning it to the developing glass, the deep sherry colour which it has will be found to have disappeared. A second application, after slight washing,

will be found to retain its colour. After a rinse to remove the iodine water, the negative is completely free from hyposulphite, and no fear need be entertained of crystallization, either before or after varnishing.

I should state that this makes the negative more dense, the iodine exercising a powerful toning action; but the half-tones are equally strengthened, so there is not the risk of hardness being produced as when an intensifier is used. This intensification may be carried still further by exposing it to the sun's rays before drying.

I have found no change of intensity on varnishing, nor after being put away for years; neither is there any contraction of the film from its use.

The stock solution is the best plate-cleaner I have ever used; I have not had a single dirty plate since using it. Although iodine is somewhat expensive, it will not be found so in use, as but a small quantity is employed. Once used, it will not be forsaken by those who, like myself, are old-fashioned enough to prefer a clean plate to an albumenized one. It may be used for removing stains from the fingers, which it does equal to cyanide, without its danger; the colour of it may then be removed from the fingers by a strong solution of hypo. In fact, it is a universal scouring or cleansing agent for the photographer.

### HASTY NOTES OF A SCRAMBLE THROUGH HOLLAND.

BY A. HARRISON.

THE land of the thrifty Dutchman does not offer very promising features to a photographic tourist whose ideas of the picturesque are confined to the beauties of nature, unless, perchance, he is content to substitute a forest of windmills for one of trees, or a spick-and-span looking cottage, radiant with paint and varnish, for the tumble-down shanties which are usually associated with rural scenery. However, if Holland is too flat and bare for fine natural scenery, the artist will find abundant work in portraying the curious characteristics of Dutch life: the extraordinary appearance of some of the towns, whose very streets seem to be full of shipping; the curious costumes worn by some of the women; and the remarkable means used to stop the encroachments of the sea, cannot fail to attract attention.

One morning in the early part of last October we steamed slowly down the Thames *en route* for Rotterdam. The journey to the mouth of the canal occupied about twenty-nine hours, and, with the exception of some brilliant meteoric showers in the early part of the evening, was about as dull as such aquatic trips usually are.

The most striking thing, on arriving at the entrance to the canal, is the means used to form an embankment. Wooden piles of about four inches diameter are driven into the mud at distances of about six inches apart, and between these are laced in different directions osier and other twigs. Upon the top of all is spread a layer of clay and earth. This kind of embankment seems more wonderful when we remember that nearly all the rivers and canals, and a great portion of the seashore of Holland, is protected in a similar manner.

It was rather dull work steaming from Helveotsluys to Rotterdam. The vessels are compelled to travel at greatly reduced speed, and stoppages are not unfrequent.

I can scarcely describe my first impression on seeing Rotterdam. Perhaps I shall be correct in saying that it seemed just the reverse in appearance to large shipping towns generally, for nowhere else do you see the shipping so thoroughly intermingled with the houses: and I think I may safely say no other shipping port presents so clean, smart, and cheerful an appearance. There are said to be as many canals as streets, and the whole town seems to be formed of quays. The photographer will find plenty of work for his camera in depicting Dutch river life. Most of the canal banks are planted with trees, which give them

a very picturesque appearance. The market is held on a canal, on the wide bridge of which stands the bronze statue of Erasmus. The high street is said to be built on an enormous dyke or dam.

The gaily painted and curiously built barges which may be seen here by the hundreds (I think I may say thousands) are externally pictures of cleanliness. The owner and his family, with the farming stock, consisting of ducks and fowls, and sometimes a pig and a cow, reside on board *en permanence*, travelling about from town to town, earning a living in much the same way as our country carriers.

On the outskirts of the town we noticed the neat, trim, and smartly painted summer houses (*huizen plaatsen*), or, as they are called, country seats, of the citizens. They are mostly situated on the borders or in the midst of the most charming of trim *parterres*, which would, perhaps, be more effective if less strictly geometrical in the forms of the beds, trees, &c., which give the gardens more the appearance of a piece of brilliant stage scenery than a natural landscape. One great failing in the summer houses (to English ideas, at least) is, that they are invariably erected on the margin of or over some vile stagnant ditch or pool, luxuriant in duckweed and offensive odours; but the Dutch ladies sip their coffee, and the men enjoy their cigars, ignorant or ignoring the existence of the poisonous atmosphere around them.

The carts for heavy burdens as often run on sledges as on wheels; and a little barrel of water is placed in the front, the drippings from which sprinkle the pave and diminish the friction.

The little mirrors fixed outside the windows of the houses, to enable the ladies to satisfy their curiosity of the passers-by without being seen, appeared to be more plentiful in Rotterdam than in either of the other towns we visited.

Leaving Rotterdam, with its curious admixture of streets, canals, ships, houses, and trees, we started by rail for Amsterdam, which city we reached in about three hours. On nearing Amsterdam, the number of windmills is most striking. They are massed together like a forest of trees. They are used by the Dutch for the same purposes as we use the steam engine, but chiefly for pumping and regulating the flow of water in the numerous canals, many of which are below the lowest tide level. We drove through the city from the station to the Old Bible Hotel, an establishment which quite bears out the recommendations of Murray and Cook.

Our first visit in Amsterdam was to the Museum of Pictures, situated on one of the quays. "The City Guard," by Helst, is the finest in the gallery. Amongst others we particularly noticed some very interesting delineations of every-day life, and amusing pictures by Teniers and Janot Steen. After leaving the picture gallery, we took a rambling walk about the city, passing the naval school, in the yard of which is a full size and fully rigged ship. Its appearance, towering above the wall that separates it from the street, is peculiar.

Our next visit was to the Crystal Palace, a building modelled after our own, only on a very much smaller scale. It is used for concerts and plays, and will hold a great number of spectators. On leaving the Palace, we waited to see a funeral cortege pass. The dress of the undertakers is peculiar; it consists of a three-cornered cocked hat with very long hat-band, a bag wig, velvet knee breeches, silk stockings, and low shoes with large buckles. The churches we visited were very plain; one had a fine set of bell chimes, and the other a finely carved pulpit. Both had many defaced monuments, some of which were, no doubt, once handsome.

We walked down the Jew's quarter of the city, but saw nothing more distinctive than is to be found elsewhere. There were, apparently, the same old clothes, odds and ends, and other lumber that one sees in London haunts. Crossing what is called the High Bridge over the Amstel,

and from whence a very good general view of the city could be taken, we walked on to the Corn Market. The square in front of the market house was lively with vendors of goods of every kind. There were stalls of pots and pans, old and new clothes, comestibles of various kinds, &c. We secured a view of this spot before we left.

Our experiences of Dutch sweetmeats may be a caution to others. Seeing some tempting white sugar-candy in a shop window, we invested in a quarter guilder's worth. Judging from the quantity we obtained for our money, we concluded that sugar was cheap in Holland. However, upon tasting it later in the day we discovered, greatly to our disgust, that we had purchased about two pounds of common washing soda, which was so highly crystallized as to look like our own white candy. No doubt the shopman thought the English a cleanly people to require so much soda.

Our next visit was to the Palace, situate in the "Dam" (a large square). It is said to be built entirely on piles (about 14,000). It is a large and rather imposing structure. It contains a large hall lined with white marble, and over the entrances to some of the apartments are some well executed and highly interesting subjects in bas-relief. Several of them represent by allegory the purposes for which the court they are in is used. The Bourse is nearly opposite to the Palace, and is comparatively a modern building.

Some of the canals in Amsterdam run close to the walls of the houses, as in Venice. The windows in the morning room of the Old Bible Hotel opened directly upon the water without so much as a ledge or step between.

The costumes of the boys belonging to one of the orphan schools is peculiar. They wear a coat half of which is red and half black, with caps to correspond. Those of another wear red, white, and black bands on their left arms.

It is said that there are over three hundred bridges in the town, and that if the sluices or floodgates were to fail, the whole city might be submerged. Allowance must, however, be made from such a statement. Most of the streets are free from heavy traffic, as great weights are chiefly conveyed by water.

Leaving Amsterdam, we made a short *detour* to Utrecht before visiting the Hague. The view from the top of the cathedral gives one a capital idea of Holland. It is said that twenty large towns can be desied. The effect of the immense network of canals to be seen gives the country somewhat the appearance of having been overspread by a huge cobweb. As is often the case in Continental churches, the sexton resides half-way up the tower. We found him an amusing old body. There are some very interesting tombs in the church, but they are sadly mutilated. The Mall consists of rows of linden trees, said to reach for half a mile. The Jansenist Bishop Remkens resides in the city. It is only here that the sect exists in large numbers (about 3,000).

Taking the rail back through Amsterdam, we reached the Hague about four in the afternoon, and put up at the Hotel Vieux Doelen, a place which is fitted up with great regard to English comfort. The remarkable feature about the Hague is that the water, instead of flowing into the sea, flows from it. Windmills on the road to Scheveningen raise the water from the dunes into an almost stagnant pool called Vyverberg, from whence it finds its way very slowly into the canal which is the high road to Delft. At Delft it is again pumped up and made to flow into the Maas somewhere above Rotterdam. The collections of pictures at the Hague surpass those of Amsterdam. The gallery consists of nearly all Dutch masters. "Potter's Young Bull," "The Anatomical Lesson," by Rembrandt, and Raphael's Transfiguration, are most notable. The collection of pictures in the Royal Palace is even more choice than those in the Museum, and our only regret was, that

inexorable time would not allow of our taking more than a cursory glance at them. The curiosities from China and Japan we did not attempt to see, but the collection is spoken of as being one of the finest in the world.

A short drive from our hotel took us to the place known as the House in the Wood. The trees that surround it are almost the only ones in Holland that are not trimmed into grotesque shapes. The Dutch try to improve nature by trimming the tops of their trees into queer shapes, and painting the trunks with bands of various gaudy colours. On our return we passed the Prison Gate (Gevangspoort); it is a very quaint and antique building, and it is said prisoners confined therein were, even at the close of the last century, subjected to tortures rivalling those of Venice. The Gothic Hall in the Binnenhof is a handsome place; the roof is pointed, and is supported by a framework of oak. I think I noticed three or four bronze statues in different parts of the Hague as we drove about, but I cannot remember any particulars of them.

Near our hotel lived a number of tame storks. They walked about the markets among the people as readily as do our tame ducks and hens; it looked rather strange to see such tall birds domesticated. The tramway took us to the fishing village of Scheveningen, about three miles from the Hague. The principal object of our visit here was to see the curious costumes of both men and women. The women have a kind of skull cap of gold or silver, the tapered sides of which project beyond the ears. To this is attached a spiral wire of about three inches high, tapering to nothing at the top; hung on the lower coils of this are a pair of very long and large pendants like earrings. The metal skull-cap is covered by a neat lace cap, and a large bonnet, which is more like a coal scuttle in size and shape than anything I know of, covers the whole, making up one of the most extraordinary of European head-dresses. The men affect the large loose trousers, with blouses of various colours; in fact, gay colours are worn by men and women alike. Carts drawn by dogs convey the fish to the towns, and the owner usually indulges in a ride home. Rather a novelty to English eyes now are these one or pair dog conveyances.

Our return journey to the Hague was made by gondola. This mode of locomotion, although rather tedious, is very pleasant for short trips.

The next day we returned to Rotterdam, and from there bid adieu to Holland. Our route to the sea was through what is called the New Cut, which avoids the bank at the entrance of the Maas. We found ourselves in London within a week from the time we started on our very enjoyable scramble through Holland.

## THE IMPEDIMENTS OF THE MAGIC LANTERN

BY JAMES MARTIN.

AN article upon this subject appeared some time since in a contemporary journal, which, had the writer been as good a mechanic as he was ingenious, had never been written. He there laid down as an axiom that the weights used to produce a flow of the gases from their bags were the great impediments of the dissolving view apparatus, and complained of their being most disagreeable travelling companions in a cab. In this respect I should consider him right, although I never had occasion to put their social qualifications to the proof, as I have always found that they could be borrowed from any tradesman dealing in heavy articles.

It has not been the weights, but the pressure-boards that I have found cumbersome and unwieldy, and could they either be reduced in size or done away with altogether, a very desirable improvement would be effected. Some considerable degree of weight is really required to keep the bags steady in their places, otherwise a slight touch might disturb them, and in all probability put out the lights.

The writer in the article alluded to proposed to substitute for weights an elastic band capable of producing a pressure of 112 pounds; this, fastened to the bottom board, was to pass over iron levers at their ends, to be drawn tight by a windlass placed on the upper board.

It does not require much depth of thought to discover that such an apparatus as this would require constant attention, and be very likely to disturb the equanimity of the exhibitor's temper, by the constantly fluctuating current of gas frequently leaving him and the spectators in the dark. I do not perceive how any alteration could be effected for the better in the arrangement at present used with the wedge-shape bags. Levers might certainly be fixed to the ends of the upper pressure-boards, to which a much smaller degree of weight than is at present used would have the same effect, but in that case the opposite ends of the under board must be firmly screwed to the floor, or the whole would topple over. Other considerations would also render this plan very undesirable.

The suggestion I have to offer, which would, in a great measure, do away with both pressure-boards and weights, is this:—Let gas-bags be of a square form, their sides made of mackintosh cloth, as at present used, but contrived to fold plaited similar to the bellows body of a camera, or, perhaps, more properly speaking, like that of an accordion. The tops made of wool about an inch in thickness, the bottom also made of wool, might form a shallow box, so that when the bag was empty and lying closely folded, the whole would appear like a box, the bag being inside of it, which would thus be preserved free from injury: it could also be locked up if required.

Open out an accordion to its full extent, then stand it on end; it will be found that it will not sink down equally, but that the upper end will show an inclination to topple over: so would that of the gas-bag—if not prevented, any weight placed upon it would slide off; therefore two rods, about three-quarters of an inch in diameter, and of a sufficient length to rise some inches above the bags when fully distended with gas, must be made to screw into the centre of two opposite sides of the bottom case, so that they may stand vertically and opposite each other; a cross-piece must be so adjusted as to bind their upper ends together, in the centre of this must be an orifice through which another rod may slide easily. The lower end of this must be firmly screwed into a socket situate in the centre of the upper board, which must have friction rollers to prevent its sides jamming in its descent against the uprights; four and seven-pound weights being placed upon the top board, and as near its centre as possible—the bag, of course, first being filled, and the tap opened. The apparatus, if properly constructed, will be found to be everything that can be desired.

A bag of this shape, two feet square, and, when extended, three feet high, will contain twelve cubic feet of gas, far more than sufficient for one evening's entertainment, and exceeds the quantity generally contained in the largest size gas-bags. The weight having direct pressure, much less is required, thereby lessening the strain on the bags. It will be seen, also, that the portability of the whole is greatly increased, as besides the bags themselves, there are only eight slight rods, which, packed together in a case, will not take up more room than a fly fishing-rod. Where expense is not an object, the whole could be nicely got up, and present a really handsome appearance.

### SOME EXPERIMENTS WITH DEVELOPERS.

BY F. WALLER.\*

HAVING, after trials of various other reducing agents, concluded that the iron, or those based upon iron, were the better, I shall confine myself to iron developer, with some trials of the various additions recommended.

The double sulphate of iron and ammonia did not present

any advantages over protosulphate, after repeated trials at various strengths. Pyro or gallic acids, for the wet process, are slow in comparison with iron. Epsom salts was tried as recommended, without any marked effect; indeed, beyond possibly neutralizing some portion of the acid, I can see nothing to be gained by its addition. A smaller quantity of acid would, I believe, produce the same results. Acetate of iron worked well, and very suitably for ferrotypes, giving excellent whites. It is prepared by adding one-half the quantity of acetate of soda that there is iron used.

The well-known method of keeping a stock solution saturated or very strong of sulphate of iron in water, and testing with an hydrometer, is handiest, the oxydization being of no harm, if not of some use. As a gauge for those who have never tried this simple plan, an ounce of iron to a pint of water will test about twenty grains strong.

Alcohol is unnecessary if the bath is in the proper trim, and acid should be used sparingly; the less the better. There is no advantage gained by a strong developer, and the results are uneven and harsh. As a rule, for the plain iron developer fifteen grains strong, one ounce of acetic acid to every sixteen ounces of solution, and mixed immediately before use.

The formula which was found to possess the most advantages was an original one, I believe. To every sixteen ounces of iron solution, fifteen grains test, add two ounces of saturated alum solution, and from one-half to one ounce of acetic acid. The alum will be found to increase the reducing power, and the development may be safely carried to almost any extent without danger of fogging. Besides giving a very soft, clean effect, it is useful for children and short exposures, and on white draperies a decided success.

A new developer is what we want, and who will step forward and supply the want? Instantaneous portraiture lies in that direction. In the meantime, let us try to improve upon our old stand by, sulph. iron. Alum will be found, I believe, a slight step in the right direction.

### CURIOUS CUSTOMERS.—THE HOLIDAY GROUP.

BY WILLIAM HEIGHWAY.\*

THE holidays! Happy time, abounding in smiles and fun, good humour and frolic. Our business is with the family group—quite enough to engross all our attention, we can assure you.

To see them as they troop in is a goodly sight—that is, to any other than a photographic eye, for we are a grumbling, morose lot! There is the mother, fond, foolish and sweet tempered; but all her best holiday humour is tried by the antics of little Frank, who is—well, all children are troublesome; and papa has under his charge little Bessie and Georgie. Aunt Maria has in tow Harry, the second in age and the first in mischief. Annie, who is quite a young lady, possessing a sweetly preposterous sense of importance as the eldest of the family, distributes herself generally in attending to the wants of her brothers and sisters. Mr. Richard, in stick-up collar and a high hat, much too important to walk with the youngsters, brings up, in dignified form, a solid rear guard, he and his cane in company.

Well, there are nine of them; and will Mr. Photographer please to place them in nice positions? for this is a most important picture, including all the family. Two or three little tears trickle down mamma's cheeks as she thinks of little Reginald, who was included in last year's picture, and is now among the flowers gathered by the Divine hand. She wipes her eyes with a subdued happiness as she thinks of the blessed promise of the season.

Mr. Photographer, who has had the prospect of this group weighing like a nightmare on his mind for the past two days, groans as he looks at the unpromising material, and finds all his plans for grouping vanish into thin and empty air. However, he knows it has to be done, or he loses a good order; and heaven knows he cannot afford to do that

\* *Photographer's Friend.*

in the present panic times; so at it he goes with commendable zeal, and meets with gratifying success. The difficulties are innumerable, but one by one they go down before his perseverance and skill like ten-pins before a well-directed ball. Certainly, Mr. Richard cannot be induced to forget his collar, which he nervously twitches every half minute; and it might be better if Frankie would not persist in swinging his legs, but that is overcome by resting those restless mottled extremities on a stool. There are, too, some misgivings that Harry's love of mischief will evince itself at a momentous crisis and ruin all; but papa has angrily warned him of dire consequences, so that now he is as sober as a judge—in fact, rather more so, as high judicial dignitaries like their little joke.

"Plate!" roars Mr. Photographer, in such a state of suppressed excitement that he could knock Pyro, the operator, down, if he is not quicker; and out comes the plate.

"Now then, children! Quiet as mice, my little dears. Watch for Santa Claus," says Mr. Photo, cheerfully.

"Oh! that's too thin," Harry mutters.

"Harry! don't be vulgar," papa says, with great sternness. "If you do not keep quiet I shall punish you severely."

"Am I all right?" asks Mr. Richard, with a wrench at his collar and a caress for his "moustache"—a sickly, weedy growth.

"All right now. Quite still, please," agonizedly admonishes the feverish artist.

"Just see that you get that moustache of Dick's niece and distinct, or the picture won't do," from Harry, unable to restrain his mischief-loving propensities.

"Harry, for my sake keep quiet; there's a dear boy; and do leave your brother alone," pleads mamma.

Dick mutters vengeance against his tormentor, and Mr. Photo perspires with dread for the result.

Now they're all quiet; a word of caution, twenty seconds of suspense, during which Mr. Photographer and the watchful Pyro dare hardly breathe; and just as Harry bursts into a big sneeze the cap is put on the lens—just in time. The deed is done, the slide restored, and the plate is taken into the dark-room.

"Is it all right?" asks paterfamilias, and the maternal hopes it is, for the dear children were all so good. Mr. Photo devoutly hopes all is well.

"All right!" shouts Pyro, husky with excitement.

Was there ever such good fortune? It's unparalleled! It's wonderful! Was there ever such a picture? Beautiful! beautiful!! beautiful!!! Frankie certainly moved his legs a trifle, and Mr. Richard's expression is rather of the smirk order; but the moustache is quite distinct, so he is satisfied. Every one is satisfied, especially Mr. Photographer as he sees the last of the family group trail out of the door.

## Correspondence.

### WHY THE AMERICAN PRINTS, TREATED WITH ACETATE OF LEAD, FADED.

SIR,—Allow me to state that I differ from your correspondent, R. M. S., in attributing the fading of the American prints, treated with acetate of lead, to their having been "immersed too long, or in too strong a solution of the lead salt." This might weaken the prints and give them a slaty look like an overtone print, but I question if it would cause subsequent fading.

The fading and discolouration are most probably due to the use of water containing carbonate of lime immediately after the removal of the prints from the lead solution. If allowed to remain some minutes in this water, carbonate of lead would most assuredly be precipitated in the pores of the prints; and if exposed to the continued action of sulphuretted hydrogen they would most probably fade.

I avoid this—as will be seen from my article in last week's issue—by the use of a few drops of acetic acid in the water; thus

removing the free lead in the print while in a soluble state. Your suggestion of using nitric acid would be equally successful.—  
Yours respectfully,  
HENRY GREGSON.

### CAUTION.

SIR,—Permit me to thank Dr. Vogel, of Berlin, for exposing a swindler in your last number. The individual referred to by him appears to obtain an introduction and reception among Continental photographers by the fraudulent use of my name, viz., representing himself as my *traveller*, and pretending to take orders for my lenses; whereas, the real purport of his visits is to sell his *nostrums*—such as varnishes, secret processes, and the like—at high prices.

Of course the lenses ordered of this impostor never arrived at their destination, and thus it happened that I became aware of his practices. The photographers who had been imposed upon in several instances addressed themselves to me direct, inquiring why certain lenses ordered of "my traveller" had not been sent, &c.

In reply to my questions as to the *name* and *address* of the individual who had thus represented himself, I received on several occasions the card transcribed at foot. I need scarcely say that his London address is purely fictitious.

However, to protect my own interest, and that of continental photographers, I caused an advertisement to be inserted in the *Cologne Gazette*, and also in *La Riforma*, warning the public against the purchase of spurious lenses, and against travellers, I never having had occasion to employ travellers for the sale of my instruments anywhere. A considerable time having elapsed without receiving any communication on either of these subjects, I inferred that my announcement had put a stop to these fraudulent practices; when to my surprise and chagrin, only a day or two ago the question of the would-be "traveller" turned up again, and this time he is among our Belgian friends. The already well-known address card was again transmitted to me, and I trust that this announcement will meet the eye of some of our neighbours, and prevent them being imposed upon by this impostor and quack, whose card I transcribe.—I have the honour to be, sir, your obedient servant,  
J. H. DALLMEYER.

(Address Card.)

## Talk in the Studio.

THE PHOTOGRAPHIC SOCIETY.—The old members of council of the Photographic Society have just issued a circular to members, announcing that they have accepted the invitation of the society to resume their position as officers, in accordance with Mr. Hooper's resolution, passed unanimously at the last meeting. As they state that they will only hold office until a new code of laws is in force, when they will resign their offices into the hands of the society at large, to permit a new general election, it is probable that in the course of a month or two a completely fresh election by the votes of all the members will take place. The next monthly meeting of the society will be held on the 14th inst., when a paper by Mr. George Bruce, of Dunse, will be read, the subject being "Printing and Toning."

PHOTO-ENGRAVING.—Amongst the finest examples of photo-engraving we have seen is a portrait of Mons. A. Davanne which appears in the *Bulletin* of the French Photographic Society for February. It is produced in the establishment of M. M. Goupil, and is described as the "Procédé Rousselon;" and the specimen in question, as well as another—a copy of a pictorial fan—is said to be quite untouched. The portrait is from a negative by Fritz Luckhardt, and seems to be almost faultless, both as photography and engraving, being at once delicate and forcible, having the general character of an exceedingly fine mezzotint engraving, to which, indeed, the copper plate from which it is produced bears a close analogy. The original idea of the process which M. Rousselon has worked out is claimed, we understand, by Mr. Woodbury. The basis of the process is a gelatine relief in which the gradation possesses a granulated character; from this the copper plate is produced, the granulated gradation giving ink-holding qualities to the image.

INDECENT PHOTOGRAPHS.—The police on Monday seized 100,000 indecent photographs on the premises at 20, Bloom-

field Terrace, Pimlico. Some of the mere objectionable portraits were recognisable as those of the owner of the house, his wife, and two sons. At Builders' Yard, Pimlico, the police subsequently seized 5,000 photographic negatives of an indecent nature.—*Telegraph*.

**OBJECTING TO PRISON PORTRAITURE.**—We learn from a provincial paper that a convict at Leeds objects to the operations of the prison photographer. The *Darlington Times* says:—"Mr. William Jones thinks there is reason in all things, and that because a man happens to be a convicted pick-pocket he should not necessarily be compelled against his will to have his portrait taken. From a circumstance which has befallen him, and Mr. Jones kicked over and broke the camera and a mirror, and now the Leeds magistrates have sentenced him to an additional two months' imprisonment for taking the only means left to protect himself against photography. Mr. Jones bears no animosity to the camera as a camera. What he objects to is being unnecessarily incommoded. As he explained to the Bench, he had already sat for his photograph to Mr. Swann at the Town Hall, and an impression might have been obtained from that gentleman if it was so urgent to procure one. So it might."

**THE TRANSIT OF VENUS.**—*Nature* says:—"Some carpenters are at present engaged in building in the Jardin de Luxembourg at Paris a photographic studio, for the use of the photographers who are to be sent out with the Transit expedition. The observations are soon to begin, and will be under the direction of M. Fizeau, member of the French Institute; but that gentleman will not leave Paris to follow the operations."

**PHOTOGRAPHY IN ART SCHOOLS.**—A new art school is in course of formation in France by the Marquis de Chennevières, Director of Fine Arts, which is intended to be intermediate to the schools already existing, and in which the students will be taught wood-carving, painting on glass and porcelain, artistic photography, picture-copying, &c.

**KENNETT'S GELATINE PELLICLE.**—Mr. Kennett says, in relation to his gelatino-bromide emulsion:—"I find as the light increases in power, and the temperature becomes higher, that the sensitiveness is becoming like a restive horse, and requires curbing by using a more powerful restrainer; and, instead of a quarter of an ounce of bromide to eight ounces of water, I am now using three drachms; and it will be found a great improvement to add to the pellicle itself about half a grain of the bromide, and four grains of loaf sugar. The sugar and bromide I add to the water in which I dissolve the pellicle; it then gets thoroughly incorporated with it. I find I can obtain great control over the development, with increase of density, and apparently no loss of sensitiveness."

**CLEMENS' PRECIPITATE FOR HYPOSULPHITE OF SILVER.**—Mr. Clemens proceeds as follows:—"To (say) twelve ounces hyposulphite solution, placed in a half-gallon jar or bottle, add from a drachm to a drachm and a-half of muriatic acid, and stir thoroughly. Settle, and add about the same quantity of sulphuric acid. Stir and settle. Take this solution to the opening of a flue, or fire-place (to carry off the noxious fumes of sulphurous gas), and add sufficient chloride of sodium (common table salt) to produce thorough precipitation. When the chemical change has been effected—*i. e.*, hyposulphite of silver has been converted into sulphuret of silver—skim off the floating substance, if any, on the solution, and save it, as it contains a small quantity of silver. Pour off the solution, and the precipitant, which is now of a waxy consistency, may be refined at pleasure."

**SIR GARNET WOLSELEY.**—The indebtedness of the public for its acquaintance with the appearance of celebrated personages to photography is thus testified by the special correspondent of the *Daily News*, in a notice of the review at Windsor of the Gold Guard Troops:—"The crowd does not yet know Sir Garnet's face or appearance. He was for an immense time riding about on the ground without being recognized in the least. I suspect that there has been hardly time for the admirable photograph of him which has been recently executed to get about in the outskirts of London; and I hear that there have been many moans from photographers that Sir Garnet's intended rapid departure has not allowed him time to sit to them."

## To Correspondents.

**G. A. T.**—One of the simplest modes of avoiding the expense of purchasing a large bath is to use a flat dish, which answers well; but if you wish for a wooden upright bath there are various methods of using wood for the purpose. The pitch-lined baths may answer, as they have been said to do; but, personally, we have had no experience with them. The cheapest mode of making a trustworthy wooden bath that we know, consists in applying several coats of shellac varnish to the inside, the varnish being made by dissolving shellac in wood naphtha. The first application may be of a thin varnish, containing about twenty grains of lac to the ounce. This should be allowed to saturate the wood; and, finally, a thicker varnish, containing about forty or fifty grains per ounce. A better wooden bath still is made by lining it with pure sheet india-rubber. This is easily done by preparing before the bath is made. The pieces of india-rubber are cut for the bottom and sides of the bath, just sufficiently large to wrap over the edges, and the pieces for front and back just the size of the wood. They are cemented each on to the piece of wood it is required to cover, and then the pieces are screwed together; the india-rubber being between all the joints served, by its elasticity, to make the bath water-tight when so screwed. It is important to avoid vulcanized india-rubber; the pure article must be employed.

**CONSTANT READER.**—You will find excellent advice on the subject of building a studio in Mr. Fry's recent articles on the subject. Bigelow's book is chiefly intended to teach principles of lighting. We do not know anything more of his studio than has already been published, but it is probable that if the proportions were stated you would find them much larger than you require. So far as we remember, the details given in an article in our last volume describe Mr. Bigelow's skylight as being eighteen feet square. 2. Undoubtedly the authorities can prohibit the practice of photography on Sundays. There is a law in existence which forbids any man following his calling on Sundays. It is not always enforced, but the authorities have the power to do so.

**E. J. S. II.**—The double decomposition of the salts produces sulphate of lead and acetate of soda. 2. Sulphate of lead is very sparingly soluble in water, but the presence of a little nitric acid enables the water to dissolve it more freely. 3. We cannot tell you the precise number of prints which should be passed through the lead solution before discarding it.

**OXONIENSIS.**—The chief defect of pictures taken with wide-angle lenses is the effect of violent perspective, which is due rather to the short focus of the lens in relation to the size of the plate. When they are used for smaller plates, the relative shortness of focus no longer exists, and the defect vanishes. With the lens of medium angle you mention we are not familiar, but we have no doubt whatever that it will give pictures on eight and a-half by six and a-half plates, quite free from exaggerated perspective. Of course it is easy in all cases to secure the true effect of perspective by holding the picture at a distance from the eyes equal to the equivalent focus of the lens.

**R. F.**—Platinum may be used for toning prints. Its tendency is to give a cold black tone, but it has no superiority over gold. We have described the results obtained by salts of several other noble metals.

**A CONSTANT SUBSCRIBER.**—Your landscape lens will answer the purpose for an open-air group. If the day is bright, you will probably be able to secure it with a very rapid exposure. Something depends on the excellence of the lens as to the size of stop you will require to secure definition throughout, but if you have any control over the arrangement of the group, you should place the figures so as to suit the lens, and so aid in getting good definition. The collodion you mention will answer well. An ordinary twenty-grain iron developer will answer every purpose. If you are not very familiar with open-air work you will find it desirable to make one or two experiments beforehand, to enable you better to understand conditions.

**JOHN WILSON.**—Of the lenses you mention, the only one suited for taking groups of four persons on card size in your studio is the first, as both the others would be, we fear, too long in focus; you would not have length enough to get the figures sufficiently small to get four on a card. For general purposes, large heads, and half and full-length cards, we should have preferred the second you name.

**G. D. L.**—There is no really effective way of making old collodion new again. If it be thin and insensitive you cannot again give it body and sensitiveness, but you may find it useful for adding to very new collodion to give it some of the qualities of ripeness. For such a purpose, a little of a very old collodion is sometimes useful.

Several Correspondents in our next.

## The Photographic News, April 10, 1874.

### M. CHEVREUL ON THE INVENTION OF PHOTOGRAPHY.

AN essay, written by the enlightened Secretary of the Academie des Sciences, and by a veteran *savant* who has from the first taken a deep interest in our art-science, deserves the notice of every photographer. For a long time past, M. Chevreul tells us, he has intended to write the pamphlet he has given to the world, for he has always considered that the claims of Nicéphore Niépce to be one of the principal inventors of photography have not been justly recognised. The author considers that we may divide sun-painting into three main sections, and apporportion to each one an inventor, thus:—

<i>Heliography.</i>	<i>Daguerreotype.</i>	<i>Photography.</i>
Nicéphore Niépce.	Daguerre.	Fox Talbot.

And as Niépce was the first to produce pictures from nature in the camera, he should enjoy the honour of priority.

Arago, who brought forward Daguerre's invention in the Chamber of Deputies, characterised all previous efforts at sun-painting as being exceedingly defective, and possessing immense inconveniences. He ignored *in toto* Niépce's name, and Gay Lussac, who announced the invention in the Chamber of Peers, made the same omission. Indeed, although Nicéphore Niépce produced permanent photographs fifteen years before, which had been shown to many scientific men, not a soul breathed his name at this eventful moment. The invention of Daguerre was, indeed, vaunted at the expense of Niépce.

It was in 1839 that an Englishman, Mr. Bauer, a Fellow of the Royal Society, who had known Nicéphore Niépce in 1827 in London, made known some circumstances which were greatly at variance with the statements of Arago. 'Under these circumstances,' says Mr. Bauer, 'I cannot think that M. Niépce was able only to give an imperfect idea of the matter fifteen years ago, for the specimens brought by M. Niépce, and exhibited in England in 1827 (and of which some are still in my hands), were all quite as perfect as the productions of M. Daguerre, described in the French journals of 1839, and yet this is the first time that the name of M. Niépce is mentioned.' Mr. Bauer had, in fact, seen, in 1827, what Arago had not been shown till 1839. Nicéphore Niépce, therefore, was not unsuccessful, and thus Daguerre was not the inventor of the permanent reproduction of objects in the camera. I will go further, and admit the opinion of Arago. . . . How was it, then, having shown the importance of the method of M. Niépce and the excellence of that of M. Daguerre, that he asked for a pension of four thousand francs for the son of Niépce, instead of only a pension of six thousand to Daguerre alone?"

M. Chevreul then goes on to state that, so far as he himself is concerned, his opinion has never varied on the respective merits of Nicéphore Niépce and Daguerre. He reviews the life of Niépce as depicted by M. Victor Fouque,\* and afterwards states that three things appear to him patent:—

"1. That the honour of originally discovering heliography belongs absolutely to Joseph Nicéphore Niépce, for he established, most perfectly, the conditions necessary for the realisation of the discovery.

"2. That Daguerre has the incontestable merit of substituting for bitumen of Judea, the substance sensitive to light, iodised silver, which was much more impressionable.

"3. Finally, that Talbot enjoys the incontestable merit of substituting for the metal or glass employed by Niépce and Daguerre, paper, by reason of which Daguerreotype is at the present day no longer used.

\* See "A Contribution to the History of Photography," by Mr. Baden Pritchard, page 133, vol. xvii. PHOTOGRAPHIC NEWS.

"It was Nicéphore Niépce who was the first to fulfil the former of two conditions necessary for fixing an image in the camera, viz., the employment of a substance sensitive to the action of light, which, after having been applied to a solid surface, is exposed in the focus of a camera, where an image falls on it; secondly, the employment of a light capable of dissolving away all the sensitive matter which has not been modified by light, and leaving that which has been acted upon.

"Nicéphore Niépce, after many years of experiment, gave the preference to bitumen of Judea as the sensitive body, which he applied to a metal plate, penetrating the material in the first place with the volatile oil of lavender, and then dissolving it in a mixture of one part in volume of oil of lavender, and nine parts of petroleum oil. The plate coated with this solution of bitumen was, after evaporation, exposed in the camera. All those portions of the bitumen impinged by the light then lost their solubility in the mixed oils of lavender and petroleum, and, therefore, on the plate being afterwards plunged into the oils, on its withdrawal from the camera, the bitumen not acted upon by the light dissolved away, while that impinged by the rays preserved the outlines of the image, and the modification brought about being in proportion to the energy of the rays acting upon the film, lights and shadows were obtained of different tones, which produced an image in relief.

"This was Nicéphore's method of operating; but this was not all the discovery. He said to himself:—'If the bitumen which covers the metal represents the image in the camera, should I not be able, by etching with an acid the metal laid bare by the development of the image, to obtain an engraved plate of such a nature that by subsequently removing the altered bitumen, which protects the metal from the corrosive action of the acid, the image would appear, the reliefs in the metal being the high lights, and the hollows the shadows?"

"Experiment justified his conjecture, and a portrait of the Cardinal Ambrose was reproduced by Niépce, in 1824, upon a plate of tin."

Thus, as M. Chevreul shows, Niépce was not only the inventor of heliography, but also of photo-engraving.

In regard to the invention of Daguerreotype, M. Chevreul reminds the reader that Daguerre had no hand in the perfection of the camera and lenses employed, the construction of the former being due to Wollaston, and the achromatisation of the lenses to Chevalier. That Daguerre made any successful experiment in heliography during the lifetime of Niépce, there is no evidence whatever to show; whereas it is proved beyond doubt that the latter made his partner acquainted with every favourable result he had obtained. When the compact was made between the two, it was distinctly laid down that any invention hereafter should be made known to the public under the name of Niépce-Daguerre, and this, as all the world knows, was not the case, when, in 1839, Daguerre published his process. The agreement stated that M. Niépce, on his part, should make known all he knew, and M. Daguerre was to contribute a new description of camera and his labour. As a fact, it was only the latter he contributed, for the new camera, M. Chevreul points out, was not due to Daguerre, but to Wollaston and Chevalier.

M. Chevreul compares the two processes of Niépce and Daguerre as follows:—"The difference between the processes is this: in that of Nicéphore the image appears on treating the plate on its withdrawal from the camera with a solvent of mixed oils, while in Daguerreotype the image, before being submitted to the action of hyposulphite of soda, is first exposed to the action of mercury, which renders it visible. If the process of Daguerre is of incontestable value, and if he has recognised the sensitiveness of the iodised plate, it is also certain that Nicéphore was the first to have recourse to iodine in his heliographic work; and if he did not employ it to such an extent as

Daguerre, still for the latter the difficulties would have been much greater if he had not been aware of iodide silver having been used in Niepce's heliographic work.

"This remark alone suffices to show how different Daguerre's position would have been had he been ignorant of the heliographic process of Nicéphore Niepce, or, having known it, he had been ignorant that iodine applied to silver might contribute to the progress of heliography.

"However this may be, Daguerre has related in a letter printed in the proceedings of the Academy, on the 23rd September, 1839, how he discovered the sensitiveness of iodised silver to light, and the employment of mercury in rendering the image apparent after the plate had come out of the camera. He states he discovered the sensitiveness of iodide silver to light in the month of May, 1831, and the action of mercury vapour in 1835. This letter is far from being clear and precise, but his intention in writing it is evident: he pretended having improved the heliographic process of Nicéphore by substituting the residue of the distillation of the oil of lavender for bitumen of Judea; and in the second place he used mercury vapour with the intention of employing the iodide plate treated with mercury in order to engrave it by means of an acid. In fact, he concluded that heliographic engraving would always be imperfect. We shall see that the inventor of Daguerreotype was not happy in his conclusion; but this letter tells us that an exposure suitably prolonged of the iodide plate in the camera will give an inverse image. If I rightly interpret Daguerre's letter when he states this, he must have been ignorant of the fact that the image is already produced upon the plate before mercuric vapour renders it visible."

M. Chevreul insists very much on the fact that iodized plates were employed by Niepce, and that his use of them naturally led to their being afterwards experimented with by Daguerre. This is one more point to show how much Daguerre had to thank Nicéphore Niepce; while heliography may be considered as the original discovery of one man. M. Chevreul is of opinion that the same cannot be said of Daguerreotype, which, although when first made known was a complete and practical process, required material improvement at the hands of Chevalier, Claudet, and others, before it was quite perfect.

To Fox Talbot M. Chevreul also assigns the position of original inventor, for although several have contributed important modifications, yet photography may be considered Talbot's method still. He owes nothing to Daguerreotype, and, as M. Chevreul very truly says: "Daguerreotype appeared for several years destined to last for ever, especially after the improvements to which it was subjected. The photography of Talbot, on the other hand, received coldly at first, improved little by little, and at last replaced Daguerreotype altogether." These words, coming from so great an authority, we should never forget.

The author finally considers that to Niepce indisputably belongs the honour of having been the great discoverer of sun-painting, or heliography, for he was the first who showed the possibility of fixing an object secured in the camera.

His concluding words are: "The rapid improvement of original inventions is in the interests of society; but in recognising them, we should always speak in favour of the inventors, and place a wide interval between their merit and that of the authors of mere improvements."

#### SOME REMARKS ON THE ART OF PHOTOGRAPHING MICROSCOPIC OBJECTS.\*

It has often struck me as a curious fact that the process of taking microscopic photographs has received so little attention from working anatomists. I think the solution

\* A paper read before the Royal Microscopical Society, by ALFRED SANDERS, M.R.C.S., F.L.S., Lecturer on Comparative Anatomy at the London Hospital Medical College, slightly condensed from *English Mechanic*.

of this enigma is to be found in the immense amount of apparatus which is supposed to be required. To look at Moitessier's book,\* or, worse still, at the paper by Dr. Berthold Benecke, in Max Schultze's '*Archiv*' (3 Bd. 1 Hft., 1867); to contemplate the paraphernalia there set forth—the condensers, achromatic and non-achromatic, the plate of ground glass, and the long array of apparatus—is enough to deter any one whose time is fully occupied from attempting the art. Other writers seem to require the whole force of a government establishment, a large darkened room, and a heliostat; they speak of employing a practical photographer one or two evenings a month to help them to reproduce all the more interesting of the month's observations, forgetting, apparently, that it might be necessary to copy fresh objects which would not keep until the photographer happened to be disengaged. I have found it possible to dispense with most of this apparatus, and to do the work with a microscope, an ordinary camera, and a deal or mahogany board.

In the succeeding remarks I do not think that I have anything absolutely new to give; yet there are many little processes, and, if I may use the term, "wrinkles," which would have saved me a world of trouble if I had been acquainted with them formerly, and which I hope will be of corresponding service to others who may be desirous of acquiring skill in the art; they are not to be found in books, and I have had to learn them by sheer experience. My apparatus is very simple; it consists of a mahogany board four feet in length and ten inches in width, which is made to double up in the centre for convenience in travelling; there is a slit running longitudinally from near one end to within three inches of the other; at the extremity three screws are arranged so as to fix down the microscope square to the board; taking an ordinary bellows camera, I have had the frame which carries the lens separate from that which carries the focussing glass, and fitted to a foot which can be fastened at any part of the board by means of a screw passing through the slit; the focussing frame has been treated in the same manner. The two parts were then connected by a treble fold of black calico long enough to reach from one end of the board to the other. This calico bag is kept apart by two rows of rings which run along a couple of brass rods attached one to each upper angle of the focussing frame. The whole is so arranged that the picture from the object under the microscope falls on the centre of the focussing glass, which is made by pouring a very thin solution of starch over a piece of patent plate, and allowing it to dry spontaneously in a horizontal position. When the apparatus is required for use it is placed on a table; the microscope is fixed in its proper position; the body, being arranged horizontally, is pushed through the opening for the lens in the front frame, and is surrounded by black velvet, so as to make the aperture impervious to light. The focussing frame is fixed at any point on the board, according to the magnifying power required; the fine adjustment is moved by means of a rod attached to the side of the board, the further extremity of which carries a small grooved wheel which moves the fine adjustment by means of an elastic band. The only other piece of apparatus required is a small glass cell filled with a solution of alum, which cuts off the heat rays of the sun without in the least diminishing the light. The eyepiece is always taken away from the microscope, as its presence diminishes the light and the definition, the increase in size of the image being obtained by a method of enlargement to be mentioned presently. With the above arrangement the one-eighth object-glass gives a magnifying power of three hundred and fifty diameters. The advantage of employing itself instead of having the object-glass fixed to a special frame, as some recommend, is obvious, for if anything occurs in one's researches a copy of which it would be advantageous to keep, it can be photographed at once (provided the sun

\* '*La Photographie appliquée aux Recherches Micrographiques.*'

shines) with less difficulty than by using the camera-lucida.

There is a good deal of trouble attendant on getting the focus properly; with the 1-5th or 1-8th and higher powers the image looks scarcely more defined on the focussing glass, when it is in focus, than when it is just out of it; a magnifying glass must be used; a watchmaker's lens, or an ordinary doublet does very well. When the object glass is just within focus, there is to be observed round the external edge of the subject to be photographed a border of white light; as the object glass is being moved away, this border diminishes in width; and just as it gets out of focus the bright border suddenly changes to a dark one. The moment must be seized when this border is on the point of disappearing, and before the dark edge is seen; at this point the object is exactly in focus. To get the best effect the adjustment for covered objects must be screwed down, and the thinnest possible covering glass (0.005 inch and less in thickness) must be employed. If this is not done, concentric lines, called interference lines, are apt to surround the subject, spoiling the effect, and damaging the negative.

I have found that no other light answers so well as sunlight for microscopic photographs. Artificial light is a delusion, with perhaps the exception of the electric light, but the trouble and expense of this precludes its employment in a private house, for at least fifty cells would be required. Magnesium ribbon gives an impression, but I have always found it impossible to get a good focus; perhaps if it could be arranged so as to give a steadier light, it might answer; Dr. Woodward appears to have succeeded with it. As before mentioned, condensers, ground glass, &c., are unnecessary, at least for the 1-8th inch and lower powers, the ordinary concave mirror attached to every microscope being all that is requisite; but even with the lowest power, this mirror should be used, as with the flat one the image of the spots of dust and other extraneous objects comes out with painful distinctness. If the object to be copied is an ordinary microscopic preparation, no especial precautions are necessary; but in cases where fresh tissue examined in fluid is the subject, it is better to paint the edge of the thin glass cover temporarily with gold size, to prevent evaporation; this is easily rubbed off after use. If the subject is not very pervious to light, a good plan is to paint the surface of the slide round it with Indian ink—in fact, to stop out all light except that which passes through the object. Hitherto I have spoken only of taking the negative; I now come to the consideration of the best way of printing. It is generally remarked that the former may have all the finest definition that can be desired, but that in the latter the greater part of this distinctness is lost. Now by the process which I am about to describe, prints can be obtained absolutely equal in point of definition with the negatives, and three or four times their size; for instance, if a negative has been taken by the one-eighth objective, doubling it will show all that is seen (being in focus) by that glass with the A eyepiece; trebling its size will show the same as with B eyepiece, and so on; but if the negative has been taken by the one and a-half inch objective, magnifying it six times will not make it show what is to be seen by the two-thirds objective, so that by this process one cannot substitute a lower for a higher objective, but simply compensate for the absence of the different eyepiece in taking the negative. The method consists simply in printing on a collodion film instead of on paper. Moitessier is the only writer on microscopical photography, that I am aware of, who mentions it. The same apparatus is used for printing in this manner as for the preceding process. The microscope being removed, a short focus photographic lens is screwed into its place; the front frame is then fixed at such a distance from the focussing frame as to give a magnifying power of (say) three diameters. Now another piece of apparatus comes into use; this is a wooden frame to carry the negative; it works in a groove

in a block of wood of such a size as to make the central point of the negative coincide with the central point of the lens; the frame for the negative is kept in place by a spring, and the block can be screwed down at any point of the slit before mentioned. The space between the negative and front of the camera should be covered with a focussing cloth, so that no light should enter the lens except through the negative. To prevent the print being reversed, it is necessary to take the impression through the back of the plate. The apparatus being properly arranged, the whole is turned at an angle towards the sky, so as to be clear of trees or other obstructions near the horizon. Direct sunlight is not required, and, indeed, is detrimental to this part of the process, although Moitessier recommends a complicated system of condensers; but these are superfluous when the enlargement required is so small.

Several precautions are necessary in preparing the plate. In the first place, the collodion must not be too thick, for, if so, it has two disadvantages: the whites of the image are sure to have a yellowish tinge, and the film is apt to slip off either in the nitrate bath or during the subsequent operations; so that it is better to add a small quantity of ether (a drachm to an ounce). In the next place, previously to pouring on the collodion, the plate must be rubbed over, by means of a bit of rag, with wax dissolved in ether. Care must be taken not to apply too much, for in that case it forms reticulated markings on the film; nor too little, or else the collodion will not come off the glass in the succeeding parts of the operation. The glass plate must be coated as thickly as possible with the thinned collodion, as it will then come off more easily. Having taken the image of the negative and developed it in the usual manner (I find the gelatino-iron developer answers extremely well for this process), the next step is the toning. This is best accomplished by means of chloride of gold, which gives a good black; platinum is, I think, not quite so good; other substances may be used, but they do not answer so well; uranium gives an ugly reddish-brown colour; bichloride of mercury, with the subsequent addition of very weak solution of hyposulphite of soda (a grain to an ounce of water), gives a good colour, but is excessively troublesome to use, as the mercury makes the film very rotten; so gold, although expensive, is the best. A grain to a drachm of water is poured over the collodion positive until the black colour is seen through the back of the plate when held over a dark material such as velvet. It does not do to hold it up to the light, for then the print may look toned when it is not so. When the above quantity will not tone any longer, some more gold must be added; but the remainder need not be thrown away, as it keeps well, and will do again another time. The effect of this process may be varied according to the subject. If the plate is exposed only just long enough to get an image, so that a prolonged development is required, the resulting print will be of a fine black colour; but if a very long exposure is given, and the development correspondingly shortened, the print is softer, and has the colour of a lead-pencil drawing, which is better for microscopic objects.

The positive having been washed and toned, the next step is to apply to its surface a piece of paper previously coated with a layer of gelatine, about twenty-five grains of gelatine to one ounce of water, to which about five drops of gelatine and a trace of chrome alum have been added. The best way to effect this transference of the film is to lay the plate in a dish of clean water, not necessarily distilled; a piece of the prepared paper is soaked in the water until thoroughly wet, and then applied to the face of the positive beneath the surface; the latter is then lifted out of the water with the paper on it; this prevents all air-bubbles getting between the two, but if any should chance to find an entrance they must be gently pressed out. The plate having been allowed to get dry, is again soaked in water for a few hours, when the paper may be

lifted off with the collodion film attached. Very often the film will come off without previous drying, but it is safer to do so; if it comes off when it is dry, as it sometimes will, we have a print with a highly polished surface, which is, no doubt, very pretty, but not so good in an artistic point of view. If the above directions should be faithfully followed, a print giving all the details of the original negative, and magnified three diameters, will be the result.

I hope, in the preceding remarks, that I have done something towards simplifying the process under consideration—a process which, although, I imagine, not destined to supersede the pencil, yet has such great advantage that it ought to be encouraged. Its advantages may be summed up in one word of great importance to scientific men, who are, or ought to be, searchers after truth: that one word is accuracy; whatever is in focus on the slide will reappear in the negative. On the other hand, its disadvantages are twofold: one, which appears insuperable, is that it only shows objects in one plane; the other is that sunshine is necessary. This in a climate like ours is very serious, but it may be overcome by patience and waiting for a fine day; nevertheless, it is sufficiently provoking to have one's work interrupted by a sudden overloading of the sky. Whoever will invent a steady light of great actinic power, which shall be inexpensive, not requiring quarts of acid, or a small steam-engine, will confer a benefit on the science of anatomy.

#### ART PRINCIPLES FOR PHOTOGRAPHERS.\*

51. We now come to the subject of composition. So far as we have gone, we have learned that what language is to the poet, so are form, light and shade, colour and accessories, to the artist. When we have mastered these elements we are ready to compose according to the requirements of our art. Nature steps in too, now, insisting upon obedience to her laws, with which one must be well acquainted before he can proceed far in the art of composition.

52. Fortunately our work is made easier from the fact that we are not called upon to make pictures continually of actors, wherein we must represent tragedy or comedy; but what we have to do is, to make our productions life-like—i.e., like the living, natural person before our cameras; and we must see that our poses, lighting, &c., harmonize with the character of the subject in hand. We should never lose sight of this law of unity, for on it, more than on any other, depends the pleasing effect of our work.

53. Success in composition requires, first, a careful observance of the rules as already treated in the various elements of art, and then an understanding of the principles of perspective, line, light and shade, variety, repose, simplicity, and harmony. Perspective and line demand the first attention, and it will be well to read the sections treating upon these over again in previous chapters.

54. When making a group, the principal figure should receive the principal light, and the picture should not be crowded any more than the lens in use compels. If the group be a large one, it should be broken up into smaller ones. When a mass of people are crowded together, and no prominence given to any one person, or any number of persons divided from the rest with reference to the effect of gradation, it is then merely grouping, and not composing.

55. Figures should be more or less varied in attitude, too, because exact repetition of lines produces monotony and formality. This variation should be governed by the subject and by the prominence of the figures. If you are making a family group, although the members thereof may wish the baby to be the most prominent figure, the correct way is to give the parents the leading position, and around

them group the rest harmoniously. The principles of nature and the laws of art both frown upon making the figures all equally prominent. Having these things all arranged, we will proceed to the lighting in our next study.

56. The study of light and shade we have referred to already, but we deem it expedient to take it up again here in its application to composition. The management of light and shade in a composition requires great care and study. The adaptation of it to the character of the subject is not only to be considered, but the quality of draperies, accessories, &c., in regard to their power of absorbing or reflecting light; the mechanical arrangement of light and shade that will be produced; and the force and nature of colours that may affect the composition.

57. Whether the picture be a group or have but one principal figure, the arrangement of light should be such as to give prominence to the principal subject, by avoiding the introduction of anything that will draw the attention away from the central figure or figures. If a group is to be photographed, such an arrangement of light must be made as will illuminate the whole, and give prominence to the figures composing the group rather than to background or accessories. As to the nature of materials that compose a group, violent contrasts, such as black and white drapery, should be avoided. The light cannot be arranged to do justice to such extremes, and the harmony of the lighting, as well as the composition, is often destroyed.

58. With a single figure the whole arrangement is more under the control of the artist than with a group, and the various points of the picture can be studied to produce the best possible effect. The nature of the light best adapted for the subject is the first consideration. If light drapery, a much more subdued light will be required than for dark, and the accessories must be arranged so as not to be entirely lost by contrast. The observation in reference to extremes of black and white apply here as well as in groups, and with white drapery anything that absorbs light to any great degree should be avoided.

59. The source and direction of the light must be considered according to the nature of the composition. According to the rules of art, a top-light produces the best effect, by allowing every part of the picture to be more clearly defined. An oblique or side light casts the shadow of one object upon another, and sometimes runs them together in confusion. In portraiture, however, care must be taken with a top-light to avoid heavy shadows on the face. In landscape photography, where the principal points are much separated, an oblique light is very effective in giving force and expression to the composition.

60. Unity of light in a picture is an established rule of art, founded on a law of nature. This rule is not so applicable to groups for portraiture, where we are obliged to light all equally well, as far as possible, as it is to the style of grouping known as *genre composition*. But in pictures of the latter class, as well as those of single portraiture, the principal figure should be placed in the focus of light, while everything else is subordinate to it. This figure then becomes the centre of observation; for the eye is ever attracted by light, and turns instinctively to it. Gradation, so indispensable to harmony, requires the same attention in lighting the different figures of a composition, so that a perfect blending, from the principal figure, in the strongest light, to that of the least importance, in the deepest shadow, may be secured, as in lighting a single face, where a harmonious gradation from the highest light to the deepest shadow is now so universally sought for and obtained. It will be readily seen, that under the proper regulation of laws, light is to the artist a language or medium of expression, the due observance of which enables him to make clear the plan of his picture, and give the interpretation he desires.

61. Objects receiving light should not be extended to the margin, because, in the first place, the lights cannot be

\* Continued from page 158.

well supported by the shades. In the next, extending the lights quite to the boundary gives the effect of an unfinished picture, which destroys the unity so essential to the harmony and completeness of the subject.

62. The lights as well as the figures should vary in form. This depends much upon the management of the drapery. In the infinitely various modes of arranging draperies, the artist may contract or extend his lights at pleasure, varying the general effect to any extent.

63. If the light and shade in a picture are well arranged and in due quantity, the effect will be pleasing, even at such distance from the eye that the subject cannot be distinguished. It is then a mere correspondence, or a balancing of light and shade. On a nearer approach, its force and powerful relief attract the eye, and fix the attention of the spectator. It will not have this effect unless it possesses the essential requisites of *chiaro-oscuro*.

64. We have considered the subject of lighting in connection with composition; we now propose to call the attention of the student to the opposite, or shadow effects, and make some suggestions in reference to the part they perform.

65. Shadows are natural attendants of light, and the student of nature will observe how one always balances the other. This is in accordance with the law of compensation that follows in everything throughout the universe, and it is only by a careful study of nature that we learn to distinguish the causes that influence us in viewing a scene, to pronounce it grand or insipid.

66. In reproducing what we see in nature by what is termed art, extensive shades contribute greatly to the beautiful as well as the grand and majestic result of the whole together; they equally serve to give richness and grace to the middle tints, and brilliancy, beauty, and animation to the masses of light. They also afford a repose no less grateful and necessary to prevent the fatigue and over-exertion of the sight on the illuminated parts. To this end, all the obscure or dark parts should be so arranged as to form one general mass, and its greatest force collected into some one part where it will have the best effect, and become a principle on which all the others are in a graduated and harmonious dependence.

67. The photographic art student will readily understand the application of these suggestions to his daily practice. Whether it be a head, a three-quarter length, or a full figure, the application remains the same. The test of skill, however, is with the first of these, for it is only in that perfect blending of shadow with light, rounding up to the highest part, where the pure light is but a mere point, and falling off through the delicate gradations of tints into the deepest shadow, that a head can claim to be artistic in composition of light and shade.

(To be continued.)

## HINTS UNDER THE SKYLIGHT.

BY E. J. CHUTE.\*

### THE EYES.

THE most important feature of the face is the eyes. In them are expressed life, love, joy, animation, goodness, and all that makes the human face attractive, and often bewitching. They also express the opposites of these, and may become equally repulsive. They are the windows of the soul. To them we always look when we would read the workings of the mind. To them the artist looks when he would measure the qualities of his sitter, and decide upon the light, attitude, and representation of character to be given him.

Among photographers the eye receives a variety of treatment. Mr. Southworth, at the convention at Buffalo, explained his method or rule of lighting the sitter to be that of screening the light till it became easy to the eyes. Mr.

Frank Jewell, in *Mosaics*, also regulates the light according to the eye, but has a little different method. He regulates the position of his sitter and the light till the "catch-light," or little white spot in the eye, appears in both; this, he claims, gives a proper light for the face. The rule is an excellent one, and may be followed with full confidence in its success, for the formation of the eye is usually determined by the character of the face. Others work from the eyes by various methods, while some pay no particular regard to them, but work more by a general study of the whole features. The eyes, however, cannot be treated with too much care, as the success of a picture very materially depends upon the clearness, depth, and life given to them. And here I may remark that this is a matter almost wholly under the control of the artist.

Dark eyes are, perhaps, subject to the greatest abuse, and are often robbed of their life and brilliancy by reflections from surrounding objects, to which they are so susceptible. These reflections are sometimes from the carpet, from light screens, or from the walls of the studio. They are often very perplexing, and the best method is to exercise all permanent tints that produce these effects, and be careful to move out of the way any offending screens. The old notion of blue walls and blue screens was a productive source of evil in this direction, and all the more so because it was deceptive. The blue reflection in the eye could not readily be seen, and yet it photographed white. From these causes have doubtless arisen the great difficulty in photographing light eyes. The reflections in them are not as readily perceived even as in dark eyes, hence they have been, in days gone by, so literally and so generally extinguished that the public had come to think that people with light eyes could never get a good picture. But the introduction of neutral tints, and the exclusion of everything that will reflect actinic light, has proved that light eyes may be photographed in all their fulness and beauty as well as dark ones.

In order to secure a natural expression of the eyes, they must be perfectly easy. A glare of light that causes discomfort should be avoided; the eyes should rest on some object that can be easily and distinctly seen, for there is nothing more trying than an effort to look at an object that is either too small, too near, or too far away to accommodate their natural focus. The artist who is observing, even if he does not understand, the construction and anatomy of the eye, will soon learn to judge from the form of the eyes about where to place the rest. In near-sighted persons they are generally round and full, like a short-focussed lens, while a long-sighted person will have eyes with the balls more flattened; but it is always well to consult the comfort of the sitter in this respect; he then feels that you are mindful of the conditions that insure success, and that you will not overlook even the smallest item that may have a bearing upon the result.

One of the evils in this connection has been the impression among sitters—arising, no doubt, from instructions they have received from time to time when before the camera—that the eyes are to be fixed upon one point, and not changed on any condition, nor even winked. Is it a wonder that we see cross-eyed and strain-eyed looking pictures? If an object be given the sitter to look at, it should not be less than three inches in diameter, nor more than six. A cabinet card is a good size; and he should be particularly told that he has the privilege of examining it all over; let the eyes wander from one point to another with perfect freedom, and winking them naturally. A full and free expression of the eye is secured by those who can see at a distance by letting them look as far away as possible; give them no particular point to fix the eye, but let it wander freely into the farthest and darkest corner of the studio. The height of the eye should also be considered, and the rest raised or lowered so as to have the direction of the sight correspond with the position of the head.

(To be continued.)

## INTERNATIONAL EXHIBITION OF PHOTOGRAPHS IN HOLLAND.

OUR photographic friends in Holland have conceived the happy idea of opening an exhibition of photographs in Amsterdam, in September next, to which they invite photographers of all nations to contribute. It will open on the 14th of September, and remain open until the end of October, applications for space to be made before the 15th of July. Mr. H. L. T. Haakman, an old correspondent of the PHOTOGRAPHIC NEWS, who is president of the commission, writes to us to aid in securing contributions from this country, and we have much pleasure both in giving the matter publicity and recommendation. Our correspondent says:—

“DEAR SIR,—By to-day's post I had the pleasure of forwarding you a prospectus of invitation to the International Photographic Exhibition.

“A couple of years ago we formed here a photographic society, and published a monthly journal. I am vice-president to the society, and president to the acting committee of the journal. The Exhibition will take place in the rooms of the Artists Painters' Association, and, as you will notice, with their co-operation, in so far that they will form part of the jury for admittance and rewards. This is quite a new feature, and we hope that it may lead to much good. Instead of our painters being antagonistic to photography, they honestly confess that the new art not only contributes much to the education of the public mind, but they admit that drawing and perspective have made rapid strides since the new art has been more generally applied; and several amongst the best of them regularly make use of photography in the composition of their paintings.

“We therefore trust that though the intrinsic value of the rewards we are about to offer be *nihil*—our means being too limited for gold or silver medals—the reward may still be appreciated, as it will be granted by neutral artists chiefly, if not exclusively, on the plea of artistic merit.

“Under these circumstances, I take the liberty, in the name of the two committees, of asking your valuable co-operation as a promoter through your kind assistance.—Very truly yours,  
H. L. T. HAAKMAN.

“Amsterdam, 30th March, 1874.”

We will publish the rules and regulations next week, and in the meantime commend the matter to our readers.

## THE PHOTOGRAPHIC SOCIETY.

THE following circular, containing the correspondence between the council of the Photographic Society and Mr. Howard, who has discharged the duties of acting secretary during the interval since the resignation of the officers at the annual meeting in February, has been forwarded to

each member of the society. Doubts on various grounds having been raised as to the legality of some of the proceedings which inevitably followed the resignation, it will be seen that the course now taken will meet any difficulty on that score, and the harmonious co-operation of all parties will, we trust, be secured in the steps yet to be taken. It is probable that the same gentlemen, with some additions, will be elected on the revising committee. The circular runs as follows:—

9, Conduit Street, W.

SIR,—I am instructed by the council to inform you that, at the adjourned annual general meeting of the society held on the 10th instant, a resolution, moved by Mr. G. Hooper, and seconded by Dr. Mann, was passed to the effect “that the president, vice-presidents, treasurer, council, and secretary be requested to resume office for the remainder of the present session, and that at the next annual meeting all officers of the society be elected in accordance with the new laws about to be framed.” This motion was communicated by the acting secretary to the late officers, and they accordingly met and gave the matter their serious consideration. Feeling that a refusal to comply with the terms of this motion might be seriously prejudicial to the welfare of the society, it was resolved that the following letter be forwarded to the acting secretary in reply to his note:—

Royal Arsenal, Woolwich, 17th March, 1874.

SIR,—In reply to your letter mentioning the request passed at the adjourned annual general meeting of the Photographic Society, that the late president, vice-presidents, treasurer, secretary, and members of council should withdraw their resignations, I beg to inform you that they consent to resume office as the council of the society until a new code of laws is in force, or until the next annual general meeting, and will then resign their offices into the hands of the members at large.—We are, &c.,  
JAMES GLAISHER,  
H. BADEN PRITCHARD.

Mr. Frank Howard, Acting Secretary.

To this communication the following reply was received:—

Photographic Society.

10, Lansdowne Road South, South Lambeth, March 20, 1874.

SIR,—On behalf of the late acting council of the society, I have to acknowledge the receipt of your letter signed

JAMES GLAISHER,  
H. BADEN PRITCHARD,

announcing the resumption of office by yourself and colleagues.

I have at the same time to inform you that I have forwarded to you the minute-book, letters, and other property of the society which came into my possession during the last four weeks.

I have also to inform you that, with the consent of the mover of the adjournment (Mr. Davis) and the chairman of the meeting, notice of the postponement of the adjourned meeting for Tuesday next will be sent to members of the society.—Yours faithfully,  
H. B. Pritchard, Esq. F. HOWARD.

The next ordinary general meeting of the society will be held on Tuesday, the 11th April, at 8 p.m., at 9, Conduit Street, Regent Street, when a paper will be read by Mr. George Bruce, of Dunse, “On Printing and Toning,” and a committee appointed to revise the laws. The report of the proceedings at the adjourned annual general meeting held on the 10th instant will be printed in the April number of the Journal.—I am, sir, your obedient servant,  
H. BADEN PRITCHARD, Hon. Secretary.

9, Conduit Street, Regent Street, W., March 25, 1874.

## VISITS TO NOTEWORTHY STUDIOS.

M. NADAR'S STUDIO IN PARIS.

THE second Parisian studio to which M. Lacan introduces us, in continuing his letters to our Philadelphia contemporary, is that of M. Nadar, equally distinguished as aeronaut and photographer. Nadar, whose real name is Felix Toumaehon, is a type of artist not quite uncommon in France, but of which, in this country, we have no examples. He is nothing, if not bold, startling, effective, even theatrical. His work is generally good; but if not of the highest quality, it is never common-place. Visitors to Paris are familiar with his name in large red letters, written diagonally across the side of a house, and written in precisely similar fashion at the back of his mounting cards. When he first adopted photography as a business, in 1852, he was a familiar character in Paris. M. Lacan says:—“He knew everybody, and everybody knew him, for he had been successively a student of medicine, a designer, a journalist, and he had made innumerable friends among the different

classes of persons who had been his companions in work or pleasure. In 1852 he rented a small house with a garden attached, situate No. 113, St. Lazare Street (a cabalistic number), and he had painted on the wall, in gigantic letters, his strange fictitious name. He made there the portraits of every one who had any celebrity. His prints, which were large for that time, presented an entirely novel appearance. Nadar worked generally in full sunlight, or, at least, by lighting the subject in such a way that one side of the face was very light and the other very dark. This resembled very much what is now called the Rembrandt portrait. These artistic pictures had a great success, and soon the new photographer felt the need of enlarging his establishment. He opened a studio on the Boulevard des Capucines, near the Madeleine. He had there, in the second storey, a glass-room and ateliers which differed only from those of his co-workers by their larger dimensions and their style of ornamentation. Everything on the inside and outside was painted red. From the vestibule, which opened on the Boulevard to all the passers-by (and in which were exposed numerous specimens), up to the iron work of the glass roof, everything presented to the eye this glaring colour. Nadar himself appeared to his visitors wearing a long woollen jacket, which, together with his great height, his red hair, his curled mustache, and his pale complexion, gave him the appearance of a stage devil, as represented at the theatre in certain fantastical pieces. The prints he made were bordered with red lines. His signature and the address were printed in red. It was, in fact, a veritable carnival of red. As the Empire was then in existence, and as Nadar was known to be a Republican, it was said to be a striking manifestation of his political opinions."

After reference to his experiments in ballooning, and the accidents which nearly cost the artist his life and that of his wife, the present studio of the eccentric artist is described. It is in the Rue Anjon St. Honre, in the most opulent and elegant quarter, a house which he has converted into a little artistic palace. "Here pink has taken the place of the red in the general decoration, and the master of the house has substituted the white cashmere jacket for the scarlet one. The house opens by a large vestibule, entered through a glass folding door. This vestibule is covered with frames, in which are exposed various specimens. On the left is a large reception-room, adorned with very fine paintings, representing the different phases of the ascension of his balloon the Giant. Works of art and high-priced porcelains (Nadar is one of our principal collectors in this line) attract the attention of the visitor. On the right of the vestibule is the sales-room, at the back of which, through curtains made of old tapestry, always open, is seen the principal room, which alone takes up the half of the ground floor. This large apartment, which resembles an art exhibition-room, is lighted from the top; a kind of gallery, formed by the slender columns that support the ceiling, surrounds it on three sides. It is there that the customers are received, and await, without impatience, the time for sitting, having to entertain the eyes and the mind exquisite paintings, curious albums, rare flowers, and works of art of all kinds."

An artist of reputation, M. Vienseuf, is at work painting the enlarged portraits in this gallery. His half-length portraits cost from one to two thousand francs, and his full-length from three to four thousand; but Nadar's customers do not object to these high prices, for they are genuine master-pieces.

"In the first storey is the main operating-room, which is upwards of fifteen yards long by thirteen wide, and about four yards in average height. The skylight, which is straight, and not inclined, as is generally the case, is hung with three rows of curtains (made of muslin and cretonne, both of a greyish tint), which move in all directions. A small moveable chamber, which is also furnished with a double row of curtains, and which can be

moved in any direction, allows the operator, according to the season, the hour, and type of the sitters, to light them under all their aspects, and at all angles, from a front light to the divers glancing lights of that known by the name of "the illumination of the foot-lights." Large backgrounds, painted by some of the best scene painters of Paris, represent, in the most natural manner, a great variety of subjects. This immense terrace can be lighted, as desired, from the north, the east, or the west.

"Nadar takes upon himself the task of removing from the water every morning the prints immersed the preceding night, and he examines each with great care, rejecting all those that seem to him imperfect. The drying is done by means of blotting-paper.

"Success has crowned his efforts, and the public hold him in high favour. It must be admitted, however, that he has neglected nothing to maintain this position. He has anticipated all improvements, and his prints have a peculiar character which renders them eminently artistic. Boldly lighted, they present startling effects, together with an exquisite purity of outside and a transparency of tone which render them most charming to the eye. They are especially remarkable for a harmony which is particularly striking in the portraits of women dressed in white. The entire gradation of whites, so difficult to obtain in photography, is represented along-side of the deepest blacks. The kind of portraits most generally made by Nadar is the album card bust, enamelled or plain, and the enlargements. All the cards made at this establishment have the date photographed in the ornamental designs which surround the picture. It is a very good idea, and is rendered more complete by the reproduction of the autographic signature when it is the portrait of a well-known person. I would mention that Nadar is the first in France who applied the electric light to photography. His experiments, at the time he made them (about 1860), attracted a great deal of attention. It was by means of this light that he was enabled to reproduce, in a numerous series of views of a highly fantastic character, the interior of the catacombs and of the sewers of Paris. He has used, also with success, the magnesium light for the same purpose."

#### PHOTOGRAPHY IN NATURAL COLOURS.

BY M. DE ST. FLORENT.\*

*Exposure.*—The paper, after having sojourned in the bath for five to ten minutes, is dried between blotting-paper, and then placed behind a painting upon glass.

If the operation is conducted in full sunlight, the thickness of the glass will have but little influence upon the clearness of the picture, because of the great rapidity of the printing; but if, on the other hand, diffused light is employed for printing, the result will be a very blurred one. In the latter case it is necessary to lay the paper next the painting itself, interposing between the two surfaces a sheet of mica, or any other substance of a thin and transparent nature.

The following plan may be adopted:—Round the margin of the painting itself are cemented strips of thick paper about one centimetre in breadth; the prepared paper is then applied in a damp state upon a glass plate, and sponged after such operation. The latter is placed against the painting with this paper frame to protect it, the slight distance between the two serving to prevent the painting from becoming damaged, while, at the same time, it is not sufficient to yield a blurred image.

The printing frame having been exposed to the light, the paper is seen to bleach rapidly, and the operation may be considered finished when the high lights of the image have become perfectly white. The print is then removed from the frame—a longer exposure jeopardising the impression altogether.

\* Continued from page 125.

The image is now plunged into water or alcohol, which removes the excess of sublimate. In this state it is capable of withstanding the action of diffused light for some minutes, and may be preserved for a long time in an album.

*Theory of the Formation of the Image.*—We will now proceed to examine the reactions which take place in the operations which we have just described.

On its exit from the mercury bath the sheet is impregnated with mercurial chloride, which is reduced by the light, giving rise to chloride of mercury and free chlorine. The latter combines with the subchloride of silver, which is transformed into white chloride. At the same time, the sub-chloride not acted upon assumes a peculiar physical condition, which permits of its being impressed by various coloured rays.

The excess of mercurial chloride having been eliminated by washing, the image is composed of chloride of silver and subchloride in a certain physical condition, and of mercurial chloride.

The calomet may be transformed into sublimate, either by the aid of chlorised water, or by means of *aqua regia*; it may then be removed by repeated washing.

The image is formed of chloride of silver and subchloride of the same metal: we shall see presently how it may be possible to preserve these compositions from all ulterior change.

If we allow a film of sub-chloride, sensitized with nitrate of mercury, to bleach completely in the daylight, and we immerse it afterwards in nitrate of silver, which is allowed to blacken in daylight, it becomes susceptible once more (after having been passed again into the mercurial bath) of reproducing coloured images.

*Employment of Alkaline Iodides.*—It is known to be possible to obtain photographic positive prints direct, by means of certain processes, the simplest of which is that of M. Lassaigne, which consists in immersing a blackened paper in a dilute solution of iodide of potassium, and to expose it afterwards to the light. This method may be applied equally for the production of heliochromic images.

For this purpose it suffices to plunge a paper coated with sub-chloride of silver for some minutes in a five-per cent. solution of iodide, after having been freed, in the first instance, by washing, from the excess of hydrochloric acid which it contains.

It is exposed to the light as above, and we obtain with a sufficient exposure an impression in which the whites are formed of iodide of silver; that blackens very slowly under the action of the light, even when the excess of alkaline iodide is removed, so as to prevent any ulterior action upon the sub-chloride forming the coloured portions of the image.

*Employment of Peroxygenic Acids.*—It is known that certain peroxygenic acids—such, for instance, as chromic acid—are reduced under the influence of the solar rays. The heliochromic process of M. Poitevin is founded upon the reduction of a mixture of bichromate of potash and sulphate of copper. We have been able lately to determine that the analogous properties of nitric and sulphuric acids are also applicable to heliochromy.

*Nitric Acids.*—By immersing into pure concentrated nitric acid a sheet of paper coated with sub-chloride of silver for the space of ten minutes, and then exposing it to light behind a painting upon glass, we obtain in a few minutes in the sunshine an image with very bright colours, the ground of which is a little yellow by reason of the action of the acid upon the organic matter. The impressions are very fine, and present passable stability if the Sutton paper previously referred to is employed. If the sub-chloride paper contains an excess of hydrochloric acid, there is ground for believing that the oxygen set free combines with the hydrogen, and forms water. The chlorine in a nascent condition then transforms the sub-chloride into chloride of silver, and the definite reaction is analogous

to that which took place with the mercurial chloride. If, on the contrary the sub-chloride employed is perfectly neutral, there is probably produced nitrate and nitrite of silver, and also a little chloride of the same metal.

*Sulphuric Acid.*—The employment of sulphuric acid diluted with a small quantity of water gives analogous results, especially upon ordinary paper. There is then formed in the whites sulphate of silver and a little chloride. We are about to undertake some experiments by the aid of compounds of the chlorine series, and we hope to encounter some accelerating agents.

*Action of Extra-Prismatic Rays.*—If we examine attentively the image obtained by one of the above-mentioned processes, we remark that all the colours appear mixed with red and violet. This result should be attributed, as M. Becquerel has observed, in his great work upon light, to the action of infra-red and ultra-violet rays. The action of these may be weakened by placing before the frame, or before the lens, according to circumstances, a vessel containing a solution of bisulphate of quinine, a substance which possesses the property of absorbing them almost entirely. As to the infra-red rays, they may be absorbed by a weak solution of sulphate of copper; a mixture of these two products will give good results.

*Impression of the Prismatic Image.*—We have not till now tried to secure an impression of the prismatic image by the aid of the processes above described. It is probable, however, that the thing would not present any great difficulty. It would be possible, even with our present very imperfect manner of fixing, to render some service to the new science known under the name of spectral analysis. We know, in fact, that in certain metals the lines of the spectrum are so numerous that it is difficult to pronounce a sound reason for the cause. Images of a fine character, obtained upon albumen, and capable of being preserved for some time, would serve to allow the spectra of the different metals to be compared at leisure. We have not yet examined the action of different sources of artificial light upon sub-chloride of silver; but it is to be presumed that they are susceptible of giving images quite as well as solar radiations.

*Addition of Chromic Acid to the Mercury Bath.*—There seems to be some advantage in adding to the nitrate of mercury bath a small quantity of bichromate of potash and sulphuric acid; the colours obtained by means of a bath thus modified appear to be more vivid.

(To be continued.)

## WHEY DRY PLATES.

BY A. DE POVORSKY-JORANKO.\*

In the photographic journals, as also in the handbooks relating to the art, there are many prescriptions for preserving the sensitiveness of dry collodion plates, or for prolonging the period of sensitiveness of wet ones. A great many substances have been poured over the surface of the collodionized plate with this object, giving more or less satisfactory results; but the incessant variety of the experiments conducted prove that the object of the experimenters has only partially been realised, and that there remains yet something to be accomplished.

You were good enough to notice in your journal my paper upon sensitized dry paper in 1869, and in that communication I mentioned whey as a preservative of the photographic film, and I had the honour to forward you some specimens which you were good enough to accept. To-day I again come before you with my whey, but this time bring it forward as a preservative of sensitized dry plates, for which purpose it seems to answer excellently well. I will describe my method of working, and enclose you some prints produced by the same, so that you may decide whether or no my process is worth publishing.

My method is of the simplest, and the results without a

\* *Moniteur de la Photographie.*

fault. It is adapted to every kind of collodion suitable for dry plates, and it gives magnificent results with bromized collodion such as that of Sutton. The harmony of tone in pure bromized collodion leaves nothing to be desired, and since I read of the Sutton process in the *Moniteur de la Photographie* I employ it for wet plates.

The glass plates are cleaned, coated, and sensitized in the ordinary way; only, if the collodion employed is bromo-iodized, it should not be freshly prepared, and should be such as will give good wet plate negatives. To clean my plates I employ Carey Lea's method—that is to say, I wash them for half an hour in a solution of sixty grammes of bichromate of potash mixed with sixty cubic centimetres of common sulphuric acid and one thousand of water. This solution effectually cleans the glass. After having well rinsed the surface of the plates on their exit from the bath in clean water, they have merely to be wiped with a clean rag impregnated with a little old collodion. If one works with bromo-iodized collodion, two or three minutes' immersion in a silver bath of eight per cent. strength is sufficient. If, on the other hand, a simple bromized collodion is used (three per cent. of bromide of cadmium) an immersion of ten minutes in a silver bath of eighteen to twenty per cent. strength is indispensable. We prefer the simple bromized collodion, on account of its rapidity and excellent results.

After having been sensitized, the plate is plunged into a bath filled with rain-water to which has been added one per cent. of acetic acid. The plate should remain at least four minutes herein, after which it is put under a rose and energetically washed for two or three minutes. The water employed may, if charged with carbonate, be acidulated until slightly acid to the taste. After washing, the plate is drained, and covered with a preservative made up as I am about to describe.

One hundred cubic centimetres of skimmed milk are taken, and to it are added one hundred grammes of rain water, and the mixture is then put on the fire. As soon as it commences to boil, one or two grammes of acetic acid, together with one gramme of citric acid, are added, which will soon turn the milk. Having separated the caseine by filtration, there is put into the liquid the white of an egg; the liquid is shaken for some moments, and then put upon the fire again and boiled five or six times consecutively, after which the whey—thus clarified and filtered—is put into a clean bottle with a few grains of camphor, and may be kept fresh, in a cool place, for perhaps two or three weeks. At the same time the preparation is such an inexpensive one that it is no serious matter if it has to be prepared fresh for every operation.

Of this whey one hundred grammes are taken, and to it 0.25 grammes of pyrogallic acid added, and the preservative is then ready for use. A small portion of it is poured upon the drained plate to chase away the water; this is thrown away, and the plate again covered with some more, sufficient to envelop the whole surface, care being taken that the preservative covers the collodion throughout.

The preservative is allowed to remain upon the plates for about a minute, and then the latter is put under a rose and again washed energetically, this operation being inherent to success. Afterwards there remains but to dry the plate in a dark place and one free from dust. In an hour the plate is perfectly dry, and will retain its sensitiveness for three months; beyond that time I have not pushed my experiments.

I must here refer to a very interesting matter. It sometimes happens that markings and lines appear on the plate after desiccation; on the development, these disappear. An observation made by M. Mosley in 1863 coincides with this experience of mine, although I am unable to give any explanation of the matter.

As regards exposure and development, the former depends, of course, upon the illumination of the object, and cannot be vigorously defined. At the same time I may

mention that the largest exposure for landscapes in the dark days of autumn and winter, with a triplet (half-plate) lens of Dallmeyer, ought not to exceed thirty seconds. I obtain vigorous and harmonious negatives after a development of four or five minutes. For interiors, everything of course depends upon the light, and the exposure may last either several minutes or several hours. The method of development is alkaline combined with intensifying in the ordinary manner with pyrogallic acid, acetic, or citric acid and nitrate of silver. I employ the undermentioned formulæ:—

No. 1.—Distilled water	...	...	100 grammes
Pyrogallic acid	...	...	0.25 "
No. 2.—Distilled water	...	...	100 "
Bromide of potassium	...	...	2 "
No. 3.—Liquid ammonia	...	...	100 "
Distilled water	...	...	100 "

To develop, I take twenty-five grammes of solution No. 1, and add one gramme of No 2; and, having put the plate under the rose to moisten it well, I treat the film two or three times with this solution, after which I add eight or ten drops of solution No. 3. I cover the plate with this mixture, and allow it to remain upon the film for thirty or forty seconds, pouring back into the developing cup and throwing it again over the plate. The image appears on the first application of the ammonia liquid, and grows more and more vigorous. As soon as the development becomes tardy, a few more drops of the solution No. 3 are added, and the operation is thus proceeded with until all the details of the image have appeared, when I stop, and wash the negative, and fix it with a fifteen or twenty per cent. solution of hyposulphite of soda. The fixing should render the image transparent, and remove the least trace of bromide of silver. Afterwards the negative is thoroughly washed, and I proceed to intensify in diffuse daylight. A solution is made of:—

Water	...	...	100 grammes
Pyrogallic acid	...	...	0.25 "
Citric acid	...	...	0.25 "

Thirty grammes of this solution are mixed with eight or ten drops of a six per cent. solution of nitrate of silver, and this mixture is poured on and off the plate, allowing it to remain thirty to forty seconds. The intensifying goes on rapidly, and one need not hurry it too much, therefore. When the proper amount of vigour has been secured, the plate is washed. A little more hyposulphite solution is poured over the film, and the latter again thoroughly washed, and placed upright upon filter paper to dry. I may add, that the collodion covered with the whey preservative withstands perfectly well all this washing, and the film, when dry, is uniform and brilliant, and is only with difficulty scratched with the nail. This may appear incredible, but the first plate will prove the veracity of my statement.

Finally, I may remark that not a plate has failed me in this method, and I feel sure that any mediocre operator working it with a little care will rarely be unsuccessful. One should never hasten the development of the plates. The more slow it is, the more satisfactory will be the result, for you can then control the image better, and correct any mistake that may have arisen from too long or too slow an exposure. The ammonia should only be introduced with great foresight and caution. After two or three plates, one becomes perfectly competent to watch and control the progress of the development, the alkaline method having a great advantage in this respect over the process ordinarily adopted by photographers.

### Correspondence.

#### IMPEDIMENTA OF THE MAGIC LANTERN.

SIR,—Kindly allow me a word or two in reply to Mr. James Martin, who, in an article in last week's number of the *PHOTOGRAPHIC NEWS*, says, in reference to the writer of an article in

a contemporary. "Had the writer been as good a mechanic as he was ingenious, his article had never been written." And by way of a beginning I would slightly alter and extend the quotation, and say of Mr. Martin, had he been anything at all approaching a mechanic, or had he *tried* the proposed gas-bag that he recommends to his readers, *his* article would never have been written. Not only does Mr. Martin show a want of mechanical knowledge, but, what is worse, he betrays a sad want of experience of the subject on which he writes. An experienced lantern operator would never say, in reference to weights for the gas-bags, "I have always found that they could be borrowed from any tradesman dealing in heavy articles." Of course he would know that weights might be borrowed, but what kind of weights? In all probability the large, round-shaped variety, slightly tapering to one end, and which can only be induced to lie on the sharply inclined boards by wedges of a pocket-knife and a bunch of keys, and sundry other gentlemen's companions, the whole structure being about as secure as a child's cardboard castle, and, in consequence, keeping the operator in a state of mental uneasiness far from conducive to a successful exhibition. The experience of a quarter of a century tells me that the right thing is to get the required weight cast in the form of two or four bars, the length of the breadth of the boards, and to take them with you wherever you go. If the operator finds them troublesome in the bottom of a cab or railway carriage, he had better stay at home, and let another take his place.

My object in writing, however, is not to controvert Mr. Martin's notions on weights—operators may be safely left to discover the right thing for themselves. My object is to guard your readers against being misled by his proposal to make square bags of the folding camera or accordion type, which could only end in the discovery that they had thrown away their money and lost their valuable time in making a thing that was utterly unfit for the purpose intended; and this I can probably best do by describing the trial and failure of one of my friends here, whom I shall call Mr. A.

Mr. A., then, is recognized on all hands as at once the most ingenious and thoroughly practical mechanic in Scotland, and that is saying a good deal. In our own clique, whenever a difficulty occurs, it is, "Send for Mr. A.;" or if one is expected, it is, "Never mind, Mr. A. will be there, and will make it all right;" in fact, his mechanical ingenuity is equal to anything—from picking the lock of a camera case to devising suitable appliances for photographing the transit of Venus. Well, some two years ago he intimated his intention to improve on the usual convenient wedge-shaped gas-bag, and if it had not been two years too early, his proposition might have been said to be a literal copy of Mr. Martin's proposal; and, being thoroughly practical, as well as mechanical, he at once proceeded to carry his idea into practice. Some of his workmen are experienced camera makers, and the result of their labour was two beautiful bags, patent cocks, polished boards, and rubber sides that folded and fitted admirably. By and by an exhibition was arranged for, and the bags were sent to me to be filled. The tube from the gasometer was attached, and so far all went well; soon the upper board began to rise, and simultaneously an uncomfortable cogginess or toppling-over tendency showed itself. This might have been remedied by upright stays; but a greater evil soon became apparent: the bellows arrangement, in short, was a failure. Although the pressure on the gasometer was not more than four inches of water, long before the bag was full the four sides suddenly sprang out in one bulge, letting the wooden top sink down, and showing unmistakably that the thing would not do. Of course Mr. A. did not at once give up his plan; many schemes were tried, but at last the rubber was stripped off and handed over to the worker in that material, who converted it into a pair of useful wedge-shaped bags, that have been in use ever since.

MORAL.—Do not try to work out Mr. Martin's proposal till he is able to report its success; and when he does, ask *cui bono*? You would still have four boards to carry, and even if they were empty they could not be carried so conveniently as a pair of ordinary pressure boards, while if full the inconvenience would be much increased.

I am very anxious for some improvement on the ordinary means of supplying gas for the oxyhydrogen light, but am quite certain that we have experimental evidence that it will not be in the direction indicated by Mr. Martin.—Yours respectfully,

JOHN NICOL, Ph.D.

SIR,—Since reading the article by Mr. James Martin in the PHOTOGRAPHIC NEWS of the 2nd inst., on the unwieldy apparatus required for the exhibiting of the magic lantern by the aid of the lime light, an idea has occurred to me, that water might be used

to give the necessary pressure to the gas bags. India-rubber bags might easily be made, which, when empty, would occupy a very small space; but when filled with water would answer the purpose of weights. Or, instead of bags, zinc tanks might be employed, of such a size as to be utilized for the conveyance of the slides, and filled with water during the exhibition.

Having occasion last year to show my own dissolving view apparatus, I found considerable inconvenience from not having proper weights with me, and was obliged to use large stones, which twice during the entertainment rolled off the bags, to the annoyance of myself and the consternation of the audience.

I have not the faintest idea as to whether water bags could practically be used, but offer the suggestion simply for what it is worth.—Yours obediently,

OXYGEN.

#### ACETATE OF LEAD FOR ELIMINATING HYPOSULPHITES.

DEAR SIR,—I am glad to see that the elimination of hyposulphite from prints is being discussed in your pages; the subject is an important one, and I feel much interest in it.

When Mr. Newton first proposed the use of acetate or nitrate of lead to effect the removal of hypo from prints, he asserted, if I am not mistaken, that the decomposition of the hypo resulted in the formation of sulphate of lead. I am more than inclined to doubt the accuracy of this assertion, for I find in the late Professor Miller's Chemistry the following statement:—"Solutions of the hyposulphites give a white precipitate of plumbic hyposulphite in solutions of the salts of lead." If this be the case it would surely only make matters worse to treat prints containing hypo with any lead salt, for by so doing we should be merely replacing a soluble hyposulphite by one which is insoluble or only sparingly soluble. Is not this a clear case of out of the frying-pan into the fire?—i.e., if the above view be correct. But even supposing that sulphate of lead be formed by the lead treatment, as Mr. Newton asserts, I think the advantage gained is a doubtful one. This salt is insoluble in water, and so must remain in the print; it is also decomposed by sulphuretted hydrogen, which is frequently present in the atmosphere of towns, sulphide of lead being formed. This would certainly cause some discolouration of the photograph. I am inclined to think that Dr. Vogel's method with iodine is also of doubtful value. The hypo is converted by iodine into tetrathionate of soda, which being only another, and probably more unstable, compound of sulphur, would require as careful removal from the prints as the original hypo.

I hear very little about chloride of lime as a means of eliminating hypo from prints. It does not seem to have attracted much attention, though I believe it to be far less open to objection than either iodine or acetate of lead, no compound being formed by its means which is injurious to the prints. It is said to weaken the prints. Why should it do so? I have never tried it myself, so I cannot say whether it seriously affects them.—Yours truly,

Warrington, March 31st, 1874.

F. W. REYNOLDS.

### Proceedings of Societies.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held at the Free Library, William Brown Street, on Tuesday evening, the 31st ult., the Rev. J. D. RILEY, vice-president, in the chair.

The minutes of the previous meeting were read and passed.

MR. GILBERT DEAR and MR. W. H. KIRKBY were elected members of the Association.

MR. J. H. T. ELLERBECK exhibited a Howard's portable tent, which he intended to use for changing and developing dry plates.

MR. LEWIS HUGHES handed round a small nugget of silver, which he had obtained by fusing his waste silver-paper with bicarbonate of soda and borax on a smithy fire.

MR. O. R. GREEN showed forty 11 by 14 views of the wildest and most beautiful scenery of the United States, consisting mostly of views of the district of Colorado, Rocky Mountains, &c., taken by Mr. Jackson, the photographer to the United States Government Survey Expedition, under Professor Hayden. Mr. Green, in describing the views, detailed the difficulties under which the photographer in those districts laboured. Not only had everything to be carried on horseback, but many miles had to be traversed, and sometimes heights of 3,000 feet to be scaled before a suitable standpoint could be obtained.

MR. FORREST and MR. KEITH both spoke of the exquisite character of the views, and of the remarkable success of Mr.

Jackson in obtaining such excellent pictures under such difficult circumstances.

Mr. W. ATKINS then explained the construction of the Woodbury sciopticon, and afterwards exhibited by its aid a number of transparencies taken by the members.

The meeting was shortly afterwards adjourned.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this society was held in the Hall, 5, St. Andrew's Square, on Wednesday evening, the 1st instant, Mr. R. G. MUIR, president, in the chair.

The minutes of previous meeting were read and approved, and the following gentlemen were admitted ordinary members:—Dr. Dickson, Messrs. A. Henderson, A. Fullerton, W. H. Moss, J. R. Wright, R. Dryburgh, J. Dryburgh, R. Simpson, J. Simpson, J. C. Pottage, and Rev. H. M. Robertson.

Mr. R. H. Bow then read a paper entitled "First Notes of Some Experiments upon the Effects of Sunlight on the Colours of Pigments, with Introductory Remarks on the Propriety of Photographic Societies Discussing Artistic Questions" (in our next). The more interesting or novel points of the paper were the facts that Prussian blue and rose madder were, in oil painting, unaffected by light; that Vandyke brown could not be depended upon, and ought generally to be replaced by a mixture of burnt sienna and black. Binoxide of mercury—the most brilliant of scarlets—though liable to turn yellow and disappear altogether in the shade, and to become brown in sunlight, is preserved from both changes by being mixed with mucilage of gum-arabic—a thick mucilage of gum-arabic—while "British gum" (dextrine), on the contrary, hastens the darkening. Mr. Bow further recommended the use of tincture of iodine for colouring the spirit in thermometers, instead of the fugitive pink generally employed, and concluded with an experiment to show what he considered the best way to use mercury as an intensifying agent—i.e., to a saturated solution of mercury bichloride (corrosive sublimate) add gradually a solution of potassium iodide, with constant stirring, till the orange precipitate first formed is just dissolved.

Mr. PRINGLE considered Mr. Bow's paper would be of much value to those photographers who were now so largely engaged in supplying the demand for coloured work. It was well known that photographs had got a bad name for want of permanence, and it would never do to let the same be said of these paintings. He hoped that Mr. Bow would not be long in giving them the second part of his researches, as they would help much to enable them to select permanent instead of fugitive pigments.

Mr. W. NEILSON heartily agreed with Mr. Bow in saying that the societies would derive much benefit from the discussion of art subjects. The Edinburgh Society had not neglected the question, but there was still plenty of room to do more. He said that artists were not altogether ignorant of the fact that some pigments were liable to fade or change, and such systematic experiments as Mr. Bow had been conducting would help them materially to make proper selections. He was afraid, however, that until they went back to the good old way of making their own colours, as the old masters had done, they could never be quite certain that their work would stand as it ought to do.

Mr. J. M. TURNBULL, in moving a vote of thanks to Mr. Bow, said, that though we were not, as a society, all artists in the sense of being painters, it was nevertheless a subject in which we were very much interested. A great many of our large photographs were either in oil or water-colours; it was therefore a subject which concerned us as much as if it had been one of a purely photographic nature. He hoped that Mr. Bow's able paper would be the means of arousing the attention of artistic bodies, and leading them to discuss and thoroughly exhaust a subject of such vital importance to them. Artists generally were too much in the habit of overlooking and despising subjects of a mechanical nature in connection with their art. Mr. Bow's experiments had clearly proved that a few weeks, or even days' exposure to sunlight was sufficient to affect more or less, and in some cases entirely to destroy, many of the colours as used in oil and water-colour painting. If the artists of the present day wished their works to be seen by posterity as they painted them, it behoved them to pay immediate attention to this subject, and, if possible, to devise a remedy. He pointed out that through the fading of even one colour in the face of a portrait it destroyed the just balance of the colour, where the flesh colour was bleached, and through the darkening of the yellow it often left the face of a sort of degraded greenish yellow, which was hideous to look at. He gave, as instances of faded paintings, two well-known works of one of our leading artists, in which he had to re-paint many of the delicate

colours. If, then, this had to be done in the lifetime of the artist, what would they be in after years, when the sun of a hundred summers had shone on them? Turner, in many of his water-colours, had made a liberal use of the fugitive lakes; so much so that Ruskin, in his "British Painters," remarks "that to see one of Turner's works in perfection, or as the artist intended it to be, it would require to be seen within a fortnight from the time it was painted." It has been the fashion to look on photographs as of a fleeting and evanescent nature; but surely the much-abused silver print has a longer lease of permanence than this. He warned photographers that most of the fine effects produced in water colour on the basis of a silver print were less stable than silver prints themselves. Many colours—particularly those of the mercurial salts—could not be applied in a moist state to a silver print without bleaching it in a few minutes; that could be seen by washing the colour off again; in fact, from the moment a silver print was covered with pigments in a moist state, a process of action and reaction commenced, which resulted in their mutual destruction. With regard to what Mr. Neilson had said about the permanence of the colour of the old masters, he thought that was mainly due to their using fewer colours, and even these few were mostly found in a natural state as earths, &c. They mostly painted in a more solid manner and with a larger body of colour, while many of our modern painters glaze their work with a colour which fades in a very short time, the colours used most in glazing being the very ones the light most affects. The great majority of our modern colours were chemical combinations, many of them with a metallic base with an organic compound, which could never be a stable colour. He hoped that Mr. Bow's labours would not end here, but that he would pursue the subject, and keep the different colours exposed to sunlight, as a longer exposure might develop a great deal more than was apparent at present, and that he would favour the society with another paper on this most interesting subject. He begged to move a hearty vote of thanks to Mr. Bow for his able and excellent paper.

The vote was carried by acclamation, and the meeting adjourned, understanding that Mr. Bow would continue his experiments, and bring the results before the society.

### Talk in the Studio.

COL. STUART WORTLEY has been appointed by the Commissioners of Patents to the Curatorship of the Patent Museum at South Kensington, vacant by the death of Sir Francis Pettit Smith.

ACETATE OF LEAD FOR ELIMINATING HYPO.—A correspondent signing "M. M. C." says:—"I see there is a good deal of controversy in the NEWS respecting the preservation of photographic prints with lead salt. I have used it for about eighteen months, and in that time have not had a print to change colour. Certainly my experience is but short, but I shall still continue to use it until it fails in its purpose. I use nitrate of lead (not acetate), and if the way in which I use it is worth having, you are welcome to it."

PHOTOGRAPHY AT THE INTERNATIONAL EXHIBITION.—The *Daily Telegraph*, in a first notice of the Exhibition, in which it professes to be not so much critical, or even descriptive in detail, as desirous of giving a general idea, thus speaks of the photographs:—"We cross to the gallery on the west side of the Hall, and find ourselves among the photographs, which well represent the condition of their branch of art, both in this country and abroad. Among the names most often occurring in the catalogue are those of A. Boucher, William Bedford, Colonel Stuart Wortley, the Berlin Photographic Company, Robert Crawshaw, and Lombardi. Such names, to say nothing of others almost as famous, are a guarantee of the excellence which those who look upon the photographs see for themselves."

PHOTO-ENAMELS.—*Anthony's Bulletin* gives the following from Mr. Atkinson, of Liverpool:—"You ask me for some information as to best enamelling process. I can only say the following gives good results: Firstly is required a clear transparency made with a toughish collodion; float the film off the glass in a solution of water strongly acidulated with sulphuric acid; wash well in several waters, and tone in a solution of bichloride of iridium and chloride of gold, in the following proportions:—

<i>Toning Bath.</i>		
Sat. (in water) sol. of bichloride of iridium	...	6 drs.
Water	...	6 oz.
Chloride of gold (dissolved in 1-oz. water)	...	3 grs.

When the silver is thoroughly toned out, wash in water 8 ounces, liq. ammonia 40 drops; wash again in several waters, then float the picture on to the surface of the enamel tablet, which dry carefully with a spirit lamp or on a hot stove; when quite dry, powder the surface of the picture with finely ground enamel glaze; then place in a muffle furnace and fire until the glaze becomes transparent, and the picture is seen in all its beauty. The enamel photograph ought to be appreciated by everyone for its permanency alone."

**STEALING PHOTOGRAPHS.**—On Thursday week, at the Mausion-House, Richard Turnbull, 29, described as a photographer, was charged on a warrant, before Mr. Alderman Ellis, with larceny as servant. Mr. Wontner, solicitor, appeared for the prosecution; Mr. Chapman, solicitor, for the defence. The prisoner was in the service of Mr. George Taylor, a photographer, of Crown Buildings, Queen Victoria Street, and Forest Hill, as chief operator, at a salary of £4 a week, down to the 20th of March. About a fortnight ago, complaints were made to Mr. Taylor of photographs taken by him being exhibited outside a shop in Park Street, Camden Town, and on going there he saw, in cases exposed in the street, upwards of two hundred copies of photographs, all his own work, and many of them of quite recent dates. The name "Richard Stuart" was upon the cases as the photographer. On the first floor he found a boy named Gidney, who had formerly been in his service, and a woman whom he had known by sight as the prisoner's wife. On returning to Queen Victoria Street he asked the prisoner if he had any connection with the studio in Park Street, and he stated most positively that he had not. He was discharged from Mr. Taylor's service next day, and he then explained that the whole thing was a mistake, for the studio belonged to the lad Gidney; and, he added, a very nice place it was. For some time past the prosecutor had been missing photographs from packets which he sent from Forest Hill to his studio in the City, and also a quantity of materials used in the business, such as solution of gold and cyanide of potassium. The prisoner was alleged to have indeed a boy in the prosecutor's service to bring him gold solution from the workshops at Forest Hill, on the pretence—false, as it proved—of wanting it to intensify negatives. After his dismissal, the prisoner, replying to a communication from the prosecutor's solicitor, addressed an insulting letter to him, telling him, among other things, that he was both a liar and a fool. On arresting the prisoner at the studio in Park Street, the police found two or three hundred portraits, some views of the Albert Memorial, a large number of negatives, some gold solution, and a bottle of cyanide of potassium, worth £50 in all, which Mr. Taylor identified as his property. In reply to the charge, the prisoner denied that he had stolen the goods, saying that he could prove that he had bought them with the business from a man named Turner. The prisoner, who reserved his defence, was committed for trial at the Central Criminal Court, bail being accepted.—*Times*.

**A CURIOUS APPLICATION OF PHOTOGRAPHY.**—In our Philadelphia contemporary, Colonel Barratti gives a novel use for photography. He says:—"I had some fruit trees that wanted pruning, and there was no intelligent or active gardener at hand; time was passing rapidly; what should I do? I photographed my trees, and sent the photographs to an establishment in Turin. The next day I received them back pruned in a masterly manner. I did the rest."

## To Correspondents.

**OPERATOR.**—We have described many modes of enlarging, and given details of their results, so far as we have seen them; but we have not personally tried every method, and therefore cannot speak with certainty as to which is the best method. We have obtained very good results in several ways. With a vigorous collodion-chloride transparency, fully exposed, and fixed only, without toning, we have obtained good results. An enlarged transparency by the wet process, slightly worked upon, and then a negative from that by the wet process, has given us good results. We have used an enlarging arrangement, made for us for the purpose by Mr. Meagher, using the light of a north sky. We have seen the magnesium light worked with advantage, and have no reason to believe that the motion and variability of the flame produced any injurious result.

**SPOTTY.**—The matt silver stains with which you are troubled are not uncommon, and may arise from various causes. The most common cause is the use of a horny, repellent collodion, causing the silver solution to run in irregular greasy looking streams on its surface. Further ripening of the collodion will effect a cure in that case, or the addition of a drop or two of distilled water to each ounce of collodion will effect a cure. The edges of the plate coming into contact with an inner frame which is not scrupulously clean will cause this result. The inner frames should be constantly washed, and the plate should rest on pieces of clean blotting-paper. An old nitrate bath, containing organic matter, is more apt to produce these stains than one in perfect condition.

**H. DIXON.**—We believe that developed prints, carefully fixed and washed, will be permanent. It is important that they should be well washed after development, and before fixing, fresh hypo solution being used for the last operation. With these precautions, we think you need have no fear of your oil painted enlargements.

**DAITMOOR.**—Both will produce very good results; but the brer process of Captain Abney is the simplest, and therefore the best to try if you do not work dry.

**A LEARNER.**—A saturated solution of protosulphate of iron often leaves a precipitated deposit of carbonate or persulphate of iron, which you may discard. 2. The precipitate in your solution of citric acid and silver is citrate of silver. Excess of citric acid will redissolve it. 3. Your bath has probably become saturated with iodide of silver by constant use. See the YEAR-BOOK for instructions for getting rid of it.

**J. GROOM.**—The address of Messrs. Dand's and Co. is 151, Strand, London.

**MR. HERITAGE.**—We regret that the pressing demands upon our time, and the entire absence of any such business relations, leave us no opportunity of aiding you in the disposal of the negatives. Write to Marion and Co., of Soho Square; possibly they may be able to use them.

**NIL DESPERANDUM.**—The print you enclose is pretty. The mode of mounting you describe would probably have a pleasing effect, but would have the disadvantage that if the glass were broken the print would probably be injured. We will not publish it until you state that we are to do so. The method of producing portraits with natural backgrounds was introduced many years ago, and at a much earlier period than you fancy. Mr. Edge introduced them some time before the firm you mention issued any. You will find several methods described in the NEWS about half a dozen years ago.

**A CONSTANT SUBSCRIBER.**—We regret to say that your grievance is an old one, and one upon which we have often written. We are powerless to help you. When an advertisement is left at our office and paid for, we, as a rule, know nothing more of the matter. We have constantly recommended operators not to send their best specimens to persons whose names and addresses are not given. Possibly, however, yours may be returned. The time which has elapsed is not long.

**W. J. BROMYARD.**—Vulcanized india-rubber is not suitable for the top of a water-tight bath, as the sulphur would contaminate the solution. If you use the vulcanized india-rubber to obtain elasticity, you can cover it with a piece of very thin pure india-rubber, or even with parhumentized paper; but the pure india-rubber is best.

**LEO.**—We do not know a work upon ceramic painting; but we believe a little manual exists. Write to Winsor and Newton, of Rathbone Place, and enquire.

**M. M. C.**—You will get full information on the subject in a little manual on the magic lantern, by "A Mere Phantom," published at a shilling by the Stereoscopic Company.

**S. H. K.**—A changing box containing the plates, with arrangement to drop them into the slide, and *vice versa*, made by most camera makers, is the most efficient arrangement. Failing that, a large bag of yellow calico to slip over the head and fasten round the waist, allowing room for working with the plate and slides, is used by some. We prefer to take three or four double backs, containing six or eight plates—enough for one ramble. 2. We do not wash prints in salt and water before toning. It generally makes the toning slower and more tedious.

**M. G.**—Some photographers use carbonate of soda—that is, washing soda—to neutralize the chloride of gold; but the plan is not a good one. Those who use it generally add a little at random, varying from one grain to ten grains per ounce. The chief disadvantage is, that the bath must be used within an hour or two, and will not keep. 2. There is no easy rule for an inexperienced person whereby to determine that a print is properly fixed. The mode of the solution flowing off the print is no guide at all. The nearest approach to a guide consists in the appearance of the print when examined by transmitted light, when it should look transparent without irregular opaque patches or spots. To a great extent you must be guided by time. In ordinary fine weather, fifteen minutes in a solution containing four ounces of hypo to a pint of water will secure fixation.

Several Correspondents in our next.

## The Photographic News, April 17, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. SMOKING IN THE STUDIO—PAINTERS AND PHOTOGRAPHERS —THE MANUFACTURE OF PYROXYLINE.

*Smoking in the Studio.*—Smoking is not a habit very frequently indulged in in the studio or dark-room, we should think, at any rate in this country, and it will interest but few, therefore, to know what the effects of such a habit might be in photographic manipulation. We see that very recently attention was called to the injurious results of tobacco smoking in the studio at a meeting of the Photographic Society of France; the ashes of the tobacco were said to fall upon the print and form little yellow spots incapable of being removed. So convinced was the photographer—she was a lady—of the deleterious nature of tobacco in the studio, that she taboo'd it altogether. One would have thought that tobacco ash was innocuous enough except under very special circumstances; however, our French sister has a different opinion. More danger would arise, one cannot help thinking, from the fumes of the tobacco, supposing the studio or dark-room to be ill-ventilated, and a delicate operation such as the development or preparation of sensitive collodion films was being proceeded with. Both the ammonia and nicotine evolved in the combustion of tobacco would be capable of influencing the sensitive film. The action of ammonia is well known to all operators, and that of nicotine would doubtless be very similar, for it is a volatile alkaloid, be it remembered. At times the action of both would perhaps be beneficial in intensifying the image, and if, as an Italian photographer has recently averred, blowing upon the film during development increases the density of the image, there would be no question as to the action of a few puffs of tobacco smoke in the course of alkaline development. But one has quite enough of volatile bodies in the close atmosphere of the dark room as it is; and passing over the danger of igniting combustible stores—such as pyroxyline, ether, &c.—we think photographers would do well to abstain from having lighted pipes and cigars in the dark room, at any rate. We were once in danger of being blown into the air by a photographer's cigar, and it is that, perhaps, that makes us appear interested in the matter. A gentleman wishing to show us some pyroxyline in a tin cylinder which he was employing for collodion, seized the tin with one hand, and with the other, between the fingers of which was a lighted cigar, he proceeded to twist round and remove the cover. Fortunately it was a good cigar he was smoking, and the long ash remained firmly attached to the fragrant weed during the operation of forcing the case open; but we have often thought the result might have been different had our friend been injuring himself with a cheap Pickwick.

*Painters and Photographers.*—"You don't know how useful photography is to us!" we recently heard an Associate of the Royal Academy exclaim, uttering the sentiment in perfect good faith. Well, perhaps we photographers do not, but most of us could give a very good guess, we think. Anyway, it is gratifying to hear an able artist make such an acknowledgment. The day, we fear, is very far distant when we shall see photographers recognized by the Royal Academy, in the same way, for example, as Associate Engravers are at present acknowledged by that body; but the thing is not altogether impossible. Gradually, photographers are making progress, and some day will make good their way across the threshold of the realms of art. We doubt very much whether there is any one among the Academicians or Associates of the present day who does not possess half-a-dozen cherished photographs, either landscapes or portraits, notwithstanding the general outcry against such pictures. Besides, art connoisseurs themselves do not appear to be always of the same mind. Thus, of late years, we have heard the artistic claims of carbon printing particularly extolled by art critics, the pictures not being so painfully sharp, but more

harmonious and subdued than silver photographs, we were told; and yet, only the other day the *Athenæum* reversed this verdict, and called all pictures in pigments, present and to come, anything in the world but artistic. We know that artists and art critics are widely different persons, but then one naturally looks for a certain general consistency in their ideas. In the illustrated papers, and in all portraits published nowadays, it would be idle to deny the influence and aid of photography in presenting truthful likenesses of distinguished persons; so life-like, indeed, are many sketches, that they at once impel the spectator to cry out, "That must be from a photograph!" We are glad to see the new illustrated paper, the *Pictorial World*, not only securing the aid of eminent photographers to illustrate its pages, but actually acknowledging with a good grace the source of the productions and the beauty of the art by which they were obtained. "There is no harm in admiring a pretty photograph, and calling it natural and picturesque, and all that sort of thing, only you must not say it is a work of art," seems to be the outcry of the painters.

*The Manufacture of Pyroxyline.*—There are now three large manufactories of gun-cotton in England: the Patent Safety Gun-cotton Factory at Stowmarket, which prepares the material in a pulped and compressed form; the Punshon Gun-cotton Company at Faversham, manufacturing the explosive in the form of powder; and the Government Factory at Waltham Abbey. Of course, in all these three cases the pyroxyline is prepared, not for the photographer, but for military, sporting, and engineering purposes; but there is no reason why these factories should not pay some attention to the preparation of soluble cotton, which alone is useful for photographic purposes. The demand for this material by photographers and medical men must surely be large enough at the present day to be worthy of consideration, and, perhaps, if its manufacture were carried on by those specially versed in the matter, there would be more guarantee of a uniform and trustworthy pyroxyline being secured. The price charged for explosive pyroxyline is about two or three shillings per pound, and photographers would be only glad to pay double this amount could they but obtain what they want.

### AMSTERDAM PHOTOGRAPHIC EXHIBITION.

The directors of the society "*Arti et Amicitia*," together with the committee of the Exhibition buildings, and with the assistance of the Society of Photographers of Amsterdam, are (as intimated in our last) organising an exhibition of photographs and articles connected therewith; and in publishing the following programme, the directors invite all photographers, both amateur and professional, to contribute:—

ART. 1.—The Exhibition will remain open from the 14th September until the 31st October. The directors nevertheless reserve to themselves the right of extending this term. No object exhibited can be withdrawn before the closing of the Exhibition, except under the express authority of the directors.

ART. 2.—Intending exhibitors are requested to make known their wishes to the directors not later than the 15th July, as also those who are desirous of advertising in the Catalogue, which will contain a list of pictures exhibited. Exhibitors should specify the number and nature of the objects they desire to send. The aim of the exhibition being to collect together as many artistic photographs as possible, the directors, in order to prevent disappointment, deem it well to inform intending exhibitors that *carte* and *cabinet* portraits will be admitted only under exceptional circumstances. Coloured or retouched photographs, like those met with in commerce, will not be admitted.

ART. 3.—The photographs should be framed, but not protected with glass.

ART. 4.—Objects which have been accepted provisionally (see Art. 2) must be addressed, carriage paid, up to and including the 1st September, "*A la Commission Directrice de la Exposition a la Societe 'Arti et Amicitia,' a Amsterdam,*" and

should be accompanied by a letter of advice signed by the exhibitor, and containing the number and description of the objects forwarded. The exhibitors are likewise requested to add any details that may be of interest regarding the objects sent in, such as dry or wet plates, instruments employed, duration of exposure, &c., and any other matters that the exhibitors may deem useful to be made known. Every object must bear the name of its exhibitor.

ART. 5.—Those exhibitors who desire to dispose of their exhibits may forward the prices of the same; in case of any purchases being made, a commission of ten per cent. will be charged. The prices must not be written upon the objects exhibited.

ART. 6.—An executive committee will be charged with the examination of the objects sent in for exhibition, and will decide as to their admission or rejection.

ART. 7.—Honourable Mentions, divided into three classes, and which will only be awarded to the producers of the photographs, will be placed at the disposal of this committee.

ART. 8.—The directors will return all exhibits free of expense where the exhibitors reside in the Netherlands, and as far as the frontier in the case of foreign exhibitors.

ART. 9.—The directors take upon themselves to insure the exhibition buildings, and will, moreover, exercise the greatest possible care of the objects entrusted to them; but they cannot be responsible for any damage or accidental loss.

<p><i>For the Direction of the Society</i>  <i>Arti et Amicitie</i>          L. LINGEMAN, President.          J. H. RENNEFELD, Secretary.  <i>Amsterdam, March, 1874.</i></p>	<p><i>For the Executive Committee</i>          H. L. J. HAAKMAN, President.          J. A. RUST,          F. A. VAN WEST, } Secretaries.</p>
---	--

## BENGAL PHOTOGRAPHIC EXHIBITION.

The following is the Report of the Judges appointed to award prizes:—

*To the Honorary Secretary, Bengal Photographic Society.*

SIR,—We have the honour to report, for the information of the Committee of the Bengal Photographic Society, that we have carefully examined the photographs under exhibition at the Dalhousie Institute, and have awarded the various prizes as follows:—

*By His Excellency the Viceroy.*—Prize A—a Gold Medal—For the best single photograph in the room. This picture is to be chosen first by the judges, and then to be excluded from competition for any other prize (open to all comers)—To H. P. Robinson, of Tunbridge Wells, England, for No. 73, entitled "Preparing Spring Flowers for Market," which, in artistic treatment, natural arrangement, and technical excellence, we regard as the finest photograph ever exhibited in this country.

*By the Society.*—Prize C—a Gold Medal—For the best series of at least six landscapes, taken and printed in India by any member of the society—To Messrs. Bourne and Shepherd, for Nos. 196, 216, 218, 227, 229, and 232.

Prize D—a Silver Medal—For the best series of at least six portraits, taken and printed in India by any member of the society—To Messrs. Bourne and Shepherd, for Nos. 234, 240, 242, 243, 245, and 246.

Prize E—a Silver Medal—For the best series of at least six photographic pictures, landscapes or portraits, taken either in or out of India by any member of the society, not being a photographer by profession, to be selected by the judges from those for which no other prize shall have been awarded at this Exhibition—To G. L. Kemp, Esq., for Nos. 155, 156, 157, 158, 170, and 171.

Prize F—a Bronze medal—For the best series of at least six photographic pictures, taken in India by any member of the society, to be selected by the judges from those for which no other prize shall have been awarded at the Exhibition—To Major Millett, for Nos. 109, 110, 111, 112, 115, and 118.

Prize G—a Silver Medal—For the best series of at least six photographs of Indian subjects, exclusive of landscapes and antiquities, taken by any member of the society—To Dr. R. Brown, for Nos. 394, 396, 397, 402, 403, and 404.

Prize H—a Silver Medal—For the best series of at least six photographic pictures of Indian antiquities, taken by any member of the society—To Messrs. Bourne and Shepherd for Nos. 188, 190, 191, 193, 197, and 198.

*By the President.*—Prize I—a Gold Medal—For the best series of at least six photographic pictures of any kind taken in Europe, America, or Australia, excepting those, if any, for which the Lieut.-Governor's prize has been awarded (open to all comers)—To H. P. Robinson, Tunbridge Wells, England, for Nos. 74, 75, 76, 77, 78, and 79. These are marvels of photographic excellence, both as art studies and in successful manipulation. No. 79 is a charming picture, and the landscape No. 74 is especially admirable.

Prize J—a Silver Medal—For the best series of at least six

photographs of young children (open to all comers)—To W. F. Westfield, for cases Nos. 437 and 438. This gentleman has exhibited also some excellent cabinet portraits, and a series of very well executed groups, as well as some very successful pictures of horses and dogs.

*By Captain J. Waterhouse.*—Prize K—a Silver Medal—For the best series of at least six landscape views taken out of India; to be selected from those for which no other prize shall have been awarded at the Exhibition (open to all comers)—To F. Beasley, Junior, St. John's Wood, London, for Nos. 52, 53, 54, 56, 57, and 61. These pictures are perfect gems of landscape photography, and, though taken by a dry-plate process, are remarkable for softness, delicacy of detail and half-tone, and aerial perspective.

*By the Honorary Secretary.*—Prize L—a Silver Medal—For the best series of at least six photographs, printed in permanent pigments, by the carbon process, or any of the photo-mechanical processes (open to all comers)—To Captain J. Waterhouse, Surveyor-General's Department, for Nos. 421, 422, 428, 429, 433, and an unnumbered reproduction, "Tobias and the Angel," by the photocolotype process. The reduced map No. 421 is wonderfully clear, delicate, and distinct, and the reproductions of Indian-ink drawings of insects are perfect. The process, which has been worked out by Captain Waterhouse himself, promises to be very valuable, especially in India, where the high temperature precludes the use of other photo-mechanical processes which involve the use of gelatine.

*By G. L. Kemp, Esq.*—Prize M—a Silver Medal—For the best series of at least six photographs, reproductions of work of art, not smaller than 12 by 15 (open to all comers)—To J. Noone, Melbourne, for Nos. 5, 8, 9, 10, 14, and 25.

We beg, also, to recommend the award of the following extra prizes:—

Gold Medal—To Marshall Wane, Isle of Man, for Nos. 72, 68, 66, 63, 70, and 64. For admirable lighting and modelling, natural and easy pose, delicate and textural rendering of dress, simplicity and subordination of accessories, No. 72 is hardly to be surpassed; No. 66 is a most successful composition picture.

Silver Medal—To W. B. Woodbury, for Nos. 182, 183, 184, 185, 186, and 187. These pictures by the Woodbury-type Photo-mechanical process are exquisite, and illustrate the remarkable applicability of the process to a great variety of subjects. Portraits, landscapes, reproductions, both from engravings and original paintings, and copies of articles of *verru* and porcelain, are all represented here, and all excellent, the most delicate gradations of tone being perfectly reproduced. It is undoubtedly the most successful of all the substitutes for silver prints, and for small plates up to 10 by 8 leaves nothing to be desired. The specimens shown exhibit considerable variety of tint, and illustrate how readily the tone may be modified to suit the subject.

Silver Medal—To W. England, St. James's Square, Notting Hill, London, for his series pictures of statuary, which are models of successful lighting and softness, and photographic skill. This gentleman exhibits also an excellent series of landscapes.

Silver Medal—To the Military School of Engineering, Chatham, for Nos. 339, 340, 341, 342, 344, 345, a magnificent series of large-sized, admirably-chosen, and well-executed landscapes. The same School has sent some very well executed specimens of Heliotype.

Bronze Medal—To D. Hedges, Lytham, for his series of photographs of animals.

Honourable Mention—To Jean Gut et Compagnie, Zurich, for a series of small portraits. These pictures deserve prominent notice, but do not fall within the terms of any of the series for which prizes were offered.—To the Surveyor-General's Department, for the series of photographs of Indian fabrics and race cups.—To Colonel Stuart Wortley, for his splendid series of large, life-size portraits, taken direct in the camera.—To Mr. Hubbard, for two small but excellent composition pictures.—And to Mr. N. K. Cherril, for an admirable series of pictures of woodland and landscape scenery.—To Mr. Douffet, for his single portrait of a lady in Oriental costume.

## PHOTOGRAPHY IN NATURAL COLOURS.

BY M. DE ST. FLORENT.\*

*Aqueous Solutions.*—If we have adopted alcoholic baths for our preparations, it is because these are prepared more rapidly, and with great regularity. But aqueous solutions may also be employed without any notable difference in the results. The employment of aqueous baths is preferable in all cases where albumenized paper is made use of.

*Employment of Collodio-Chloride of Silver.*—Heliographic images upon paper or glass may be obtained by employing collodio-chloride of silver. The impressions upon glass are very delicate, but they lack intensity. The formula of M. Van Monekhoven was adopted for these experiments.

It is admitted that the production of images upon glass of a stable nature is the desideratum in heliography. If, indeed, we could obtain a view or portrait under these conditions, the cliché might be considered a matrix from which an indefinite number of prints could be obtained by means of the processes above described for securing copies of painting on glass. The impressions would be produced in their true sense.

*Fixing the Images.*—The problem of fixing appears to be a great difficulty to solve in a complete form. It may, however, be deemed, to some extent, overcome from a practical point of view, as the prints are capable of being preserved for an indefinite period in an album, while they are also capable of sustaining an exposure to diffused light of a pretty long duration. We will record certain experiments which we have made in the matter.

To fix the image, it is necessary to find a substance which leaves the sub-chloride intact, whilst it dissolves away the chloride, or transforms it into a product easily eliminated. It is necessary, moreover, to prevent the ulterior reduction of the sub-chloride forming the coloured image, but, these results obtained, it would not then even be conclusive as to the stability of the impressions.

In the present state of science, one hardly knows, in fact, how to explain the effects of colouring which the sub-chloride of silver presents under the influence of active rays, and the ingenious hypotheses which are made on this subject do not serve to guide one in the selection of a fixing agent. It may be remarked, nevertheless, that in most cases the colours do not disappear until the sub-chloride has been altered in consequence of a reducing or oxidising action taking place. An attempt might, however, be made to preserve the material from subsequent chemical change, and this we have tried to effect.

The image, on coming out of the printing-frame or the camera, is but very slightly stable; it disappears in a few seconds if exposed to the light, and in a shorter or longer period when kept in darkness, by reason of the action of the bichloride of mercury. A simple washing in water or alcohol fixes it a little, and then it becomes possible to preserve it for a long time in an album.

*Employment of Ammonia and Alkaline Chlorides.*—More stability is given to the print if it is plunged, after washing, into a weak solution of ammonia, prolonging the immersion for several hours, and then passing it into a concentrated solution of chloride of sodium or potassium, which is allowed to act as long as possible, removing the same frequently, and maintaining it at a temperature of about 60° Centigrade. The alkaline chlorides dissolve, in fact, especially when warm, the chloride of silver, without sensibly attacking the subchloride, in such a manner that on coming out of the bath it blackens slowly enough in the light, especially if exposed to a newly-prepared chloride bath.

It is well to free the print, in the first place, from any calomel it may contain, which blackens on contact with ammonia, or becomes yellow more or less rapidly under the influence of light. This is done, as we have already pointed out, by transforming it into mercurial chloride, either by means of chlorine water or *aqua regia*.

*Employment of Chloride of Lead.*—Chloride of lead obtained by double decomposition in the pulp of paper, nitric acid, sulphuric acid, &c., also has a fixing impression upon the image. M. Niepee de St. Victor has already indicated how to accomplish this object with a varnish of chloride of lead and dextrine.

*Action of Gelatine, Albumen, Varnish, &c.*—The stability of the impressions is notably improved if they have been obtained upon paper strongly albumenized or gelatinized. Finally, a much greater degree of permanence is obtained if the print is covered with a thick varnish, either of gelatine mixed in certain proportions with chloride of ammonium and bichloride of mercury, or with any substance susceptible of liberating an oxidizing agent under the influence of light.

We will now make a few remarks in reference to recording the re-actions which are produced. The light tends to reduce the subchloride of silver, and also the white chloride, if this has not been completely eliminated. In consequence, free chlorine is produced, which combines with the organic matter serving as support, or escapes into the air. It is therefore necessary to seek to render, every moment, to these substances the quantity of chlorine which they lose, and this, it will be admitted, could be done by superposing a compound capable on reduction by light to give out an oxidizing agent, chlorine or oxygen. In this way it is possible to explain the preservative action of the mercurial chloride, very dilute nitric acid, and finally sulphuric acid, or sulphate of mercury, proposed by M. Poitevin.

If the proportion of these substances is too great, the oxidising agent in excess will exert a subsequent oxidising action upon the subchloride, and will make the image disappear. The varnish, albumen, gum, dextrine, and especially gelatine, then act in the capacity of restrainers, in modifying the action.

It is known, indeed, that all these substances are oxidised under the influence of solar rays. It is also known that, according to the experiments of Niepee de St. Victor, after an exposure to the sun for some period, they acquire the property of very marked reducing agents. Their oxidation consists, therefore, in the liberation of a portion of the reducing element, hydrogen. This hydrogen, we can understand, influences the re-actions by weakening the effect produced upon the subchloride by the chlorine or oxygen in excess.

Whatever may be thought of the explanation which we have just given, experience proves that if a thick film of gelatine is poured upon a heliographic print which has not been freed from its excess of mercurial chloride, it becomes stable enough to support, without very much alteration, an exposure of several hours to solar influence. The fact is rendered the more apparent if we cover only a portion of the image with a film of gelatine and expose it to the light. The uncovered portions bleach completely in a few moments, while those which are covered by the preservative coating of gelatine remain, and resist the action of light for several hours. The high lights, however, after a time blacken by degrees, and the print disappears in a greater or less period.

The proportion of oxidising agents is not large enough, as a matter of experience, to make good the losses sustained by the chloride and subchloride of silver; but we may assume that, guided by the theory of equivalents, it will be possible, after a number of essays, to arrive at such proportions as will secure stability for all practical purposes.

## EFFECTS OF SUNLIGHT ON THE COLOURS OF PIGMENTS.

BY R. H. BOW, C.E., F.R.S.E.\*

It has often appeared to me as a strange thing that, while the followers of almost all the other professional and scientific occupations form themselves into societies for the discussion of questions of practical or speculative interest to them, the different associations of artists appear to manifest little interest or industry in extending their knowledge of the scientific and practical departments of their calling. This impression which I entertain may, very possibly, be erroneous; but, if so, I plead that it arises from their discussions and advances in knowledge being kept too much to themselves.

Assuming that there is remissness on the part of the artistic profession in not keeping the departments of science with which they should especially deal abreast with the main body in the rapid forward march of the present times, I submit that the photographic societies may very legitimately step in and take up the neglected work. On the

\* Read before the Edinburgh Photographic Society.

one hand we find many true artists enrolled in their membership, so that they are quite capable of dealing in a liberal spirit with aesthetic questions and discussing the laws of art; and, on the other hand, photographic societies are so abundantly supplied with the scientific element that they are well prepared to work in the fields of chemical and mechanical research in connection with the materials and processes employed at the easel.

There can be no doubt that the importing of this new work into the lists of subjects to be dealt with by our societies would infuse new life into their meetings, and save from the weakening effects sure to arise from too much recidivism of older and somewhat worn-out topics. And this extension of their sphere of activity would be a natural and healthy development of photographic societies. At their first institution they very properly confined their attention to subjects lying within the narrower limits of what was specially photographic, and chiefly in connection with the reactions of their particular chemicals and the mechanical and optical arrangements of their apparatus; but soon they began to feel an interest in chemical and optical information outside of their art profession, and from artists—who at first stood aloof or in antagonistic attitudes towards them—at length enlisting in their ranks, the subjects dealt with assumed more frequently an artistic character, and the connecting bonds between photography and the older sister arts are becoming every day stronger and more numerous. The photographer often now employs the artist to complete his work, and the artist is learning to lean more and more upon the aid of the photographer; and the combination of the artist and the photographer in the same individual is becoming less an exceptional than a common occurrence. The photographic art societies may now, therefore, have arrived at that period of their growth when they may presume freely to range over and explore the subjects that in times past have been regarded as the special preserves of the artist.

There are two or three subjects of this class that I have thought of venturing to break ground upon before the Society; but that which I have chosen for to-night belongs to a sort of debatable land—it takes up a small part of the inquiry into what mischief our particular friends, the so-called chemical rays, are working upon the artist's colours.

#### EFFECTS OF SUNLIGHT UPON THE COLOURS OF PIGMENTS.

The undertaking a subject like this is very apt to end in experiences such as a traveller should meet with who suddenly resolves to explore a distant mountain range. From his starting-point the work seems circumscribed in extent, and of simple and pleasant execution; but soon after beginning the actual exploration, he acknowledges that a portion only of his original enterprise will suffice to swallow up all the time at his disposal, and, as he penetrates into the gorges, and loses his bearings amidst the nearer subordinate elevations, his energies become engaged upon and engrossed by the minutest details. So the subject of the effects of sunlight upon the colours of pigments, although at first sight it appears a simple and not very extensive one, is no sooner attacked than a number of unexpected points of interest come into view, and questions arise which would require for their satisfactory solution the carrying out of a great many experiments of long duration. I find, consequently, that I have only made a beginning, of the work, and, from not foreseeing the complexities of the subject (especially those arising from the very different influences exerted by the mediums with which the pigment may be mixed), this beginning is far from a systematic one.

The pigment, or colouring matter, may be presented to the influence of the sun's rays under various conditions:—

1. It may be in a liquid or dissolved state, the menstruum being water, spirit of wine, or other fluid.
2. It may be presented as the pure powder, or as a stain or dye upon paper or other absorbent body.
3. It may be in combination with gum, gelatine, or other medium soluble in water. Such addition, while it serves to

mechanically fix the powdery pigment, has the further effect of protecting it more or less from the air and gases—and possibly also of obstructing molecular changes.

4. It may be combined with pure drying oils, or with spirit or turpentine varnishes.

5. The oils or varnishes may be combined with other substances that may chemically affect the pigments—as when the oil is boiled with litharge or mixed with sugar of lead or other dryers.

6. The pigment may be presented as in encaustic work, or in the form of enamels or glasses.

In a systematic treatment of the subject it might be proper to conduct the experiments upon each pigment under as many of these headings as its nature would admit of. The few experiments which I have made will, however, be ranged in the two classes of ordinary oil and water-colour painting. They were originally undertaken in 1871, simply to satisfy myself as to the permanency or otherwise of some of the ordinary tube colours used in oil painting, as I had at that time resumed the brush as an amateur. The results were considerably different from what I had been led to expect. Since being asked to contribute a paper, I have endeavoured to extend the scope of the experiments; but the time for this has been too limited, and, instead of clearing up the subject, these have rather served to raise doubts, and show that it is a very complicated one.

In conducting the experiments the obvious arrangement was to paint the colours on a suitable board, in the form of bands across it, and obscure a portion of each band when the board was exposed to the light.

The experiments of 1871 were conducted so that one-half of each band of colour should lie over a coating of glossy whitelead paint, while the other half was upon white cardboard, so much magill being used that the half upon the painted ground dried with a gloss, while that on the simple cardboard had a dull surface. Part of each half was obscured, but it may here be stated that this different treatment of the two halves had no marked effect upon the results. This set of experiments will be referred to as sheet A.

Of the recent experiments begun on February 23rd, those with oil colours will be referred to as on sheet B. In these Robertson's medium was used to mix with the colours and pigments, and, after drying, this was further used as a varnish over them. Sheet C contains the recent experiments with water-colours and dyes. The amount of exposure to the sun which sheets B and C have received has not been half of that which might have been secured by frequently shifting them so as to face the sun when it happened to shine.

In giving the results it may be best to collect together all that is to be said of each particular pigment; and, taking first the browns, the most important of these, from its almost universal use, is—

*Vandyke Brown.*—In the experiments with this, in 1871, I was much surprised to find it soon lose both in depth and quality. In sheet B the colour was not nearly so soon affected, and, although the change is quite observable, it is not very important up to the present date. In the water colour sheet C the loss of depth of colour is much greater. The general result is, that vandyke brown fades in the sun, but that this may be retarded by a coating of varnish. The pigment does not, however, deserve the confidence that artists have placed in it; and a very fair substitute may be had in the mixture of black and burnt sienna, used by our esteemed member, Mr. Norman Macbeth. Such a mixture possesses very considerable transparency, its permanence is assured, and browns of any quality as regards warmth or coolness may be made; but one or two definite mixtures, put into tubes, so that the artist might have a readier knowledge of what he is about, would be desirable.

(To be continued.)

#### SPECTRUM ANALYSIS AND PHOTOGRAPHY.

BY J. NORMAN LOCKYER, F.R.S.

A COURSE of Cantor lectures on "Spectrum Analysis as Aided by and Aiding the Arts," delivered before the

Society of Arts, contains much interesting information in relation to photography as applied to the registration of results in spectrum analysis. In commencing, Mr. Lockyer recalled a paper read before the society on photography by the late Mr. Claudet thirty years ago. In that lecture, Mr. Lockyer said, "he gave an account of the progress which had been made up to that time in an art and a science which is now perfectly familiar to all of you; I refer to photography; and it is excessively curious that his lecture on the origin of this science, and my present lecture on the application of photography to spectrum analysis, are complementary to each other, so much so that one may almost say that Mr. Claudet's lecture, admirable though it was, was incomplete, because he did not show in it—as of course he could not show—how certain matters which he referred to in that lecture have been dealt with in the light of modern science." Mr. Lockyer proceeded:—

If you carry yourselves back to the year 1839, some four years before this lecture to which I refer was delivered, you will recollect that M. Niepce had at that time brought photography to a more practical realisation than it had been by any of his predecessors. He had then for some years allied himself with Daguerre, and the Daguerreotype was already in existence. The action of iodine on silver, first discovered by Fox Talbot, had been fixed by the vapour of mercury.\* Now, in the Daguerreotype we had not the action of light in its ordinary sense; and men's minds were very much exercised as to what could be the real cause of the effects which were then being revealed. Mr. Claudet, in his lecture, points this out in a most admirable way, and I will summarise, if you will allow me, just some of the principal points to which he alludes. You had a beam of light falling on a plate. On this plate was a certain chemical compound. What part of the sunlight, or was it sunlight at all, which so acted upon this compound, that you got an image more or less permanent? What more natural than that this question should be investigated by means of various tinted glasses? The solar beam which the experimenters then used they made to pass through glass, now of one colour, and now of another. I can show you, by means of this electric lamp, nearly what they did. Imagine the lamp to be the sun; in the path of the beam differently coloured glasses are placed. We have now the action of a red glass; we now change the red glass for another one, and now we have the action of a green glass. There was an immense deal of difference of opinion concerning the action of light as investigated in this way. In fact, I shall have shortly to show that Mr. Claudet and a very distinguished French physicist, M. Becquerel, were considerably at variance with regard to one particular point which came out from this kind of investigation. But we had not long to wait. Sir J. Herschel, in the year 1839, pointed out that it was not a question of investigating these new qualities of light at all by means of coloured glasses; they should be investigated by means of the spectrum. Sir J. Herschel, in three papers, communicated to the Royal Society in the years 1839, 1840, and 1842, showed that the only philosophic way of investigating this problem was really by obtaining a pure spectrum, such a one as I now throw upon the screen. You see that we have at once, in different parts of this spectrum, exactly what we get at different times when we deal with red glass, yellow glass, orange glass, green glass, blue glass, and so on. And having such a spectrum as this to deal with, and supposing such a spectrum thrown on to the photographic plate, it is quite clear to all of you that if there was something magical or unknown in the red rays which gave us this new action on the molecules of the particular chemical compound employed, or whether this magic really resided in the blue rays, that we should at once have this pointed out to us in the most unmistakable manner, by the action in the part of the plate on which the red image fell, or in the part of the plate on which the blue image fell.

Now, although Sir John Herschel was the first in this country to point out the extreme importance of this point of view, he was by no means the only one. Then, as now, there were distinguished Americans who were well to the front, and among them was Dr. Draper, the father of another Dr. Draper whom I shall have to speak of by-and-bye. Those of you who are familiar with the enormous step in advance which was taken in spectroscopic investigations by Wollaston, who substituted a slit for a round hole, will perhaps be somewhat surprised to find that the first observations were conducted by throwing a converging beam of

sunlight, giving an achromatic image of the sun on the plate, through a prism. This method of procedure of course did not go so far as a better one might have gone, but it went a considerable way. Sir J. Herschel, from his observations made in this manner, stated that he had found a new kind of light—a new prismatic colour, "lavender grey," altogether beyond the blue end spectrum, such as you have seen it on the screen—altogether beyond the blue end of the spectrum, not the red end. Professor Draper, on his part, also came in the main to the same conclusion, stating that he had discovered a "latent light."

When we have come from the year 1839 to the years 1842 and 1843, we find a great advance, an advance just the same as far as photography goes, as Wollaston's advances on Newton was with regard to spectroscopic observation. Both Becquerel and Draper introduced, instead of this achromatic image of the sun, the simple arrangement of throwing sunlight through a slit and a proper combination of lenses on to a plate. The result was that on the 13th of June, 1842, Becquerel did what I may venture to call a stupendous feat.\* He did what has never been done since, so far as I know. He photographed the whole solar spectrum with nearly all the lines registered by the hand and eye of Fraunhofer. I do not mean merely the blue end of the spectrum, as you may imagine, but the complete spectrum, from the "latent light"—the ultra violet rays of Draper—to the extreme red. Draper also did something like the same thing, but not quite the same thing, in what he calls a "tithonographic representation" of the solar spectrum. He gives certain lines in the extreme visible blue part of the spectrum,† certain other lines, which none but Becquerel had ever seen before (Draper's work being done nearly a year later), and in the extreme red—beyond the visible red of the spectrum, he gives other lines which even Becquerel had not photographed. This of course was such a tremendous revelation to both these men that you can imagine considerable discussion arose, not only in their own minds, but in the minds of others, with regard to the work which they had done. Becquerel found, from an absolute comparison between the Fraunhofer lines which he had photographed and the Fraunhofer lines which Fraunhofer himself had registered, tremendous evidence in favour of the fact that this new chemical agent which was astonishing the world, whatever it was, was not something absolutely and completely independent of the visible rays. Draper, on the other hand, in his "tithonographic representation," had, for some photographic reason or other, not succeeded in registering the lines in the yellow, orange, or green part of the spectrum, although he had fixed the lines in the blue, in the extreme violet, and in the extreme red; and he considered himself justified by his experiments in coming to exactly the opposite conclusion to that at which Becquerel had arrived, namely that the light, whatever kind of light it might be, which was at work in effecting this chemical change which rendered photography possible, was something absolutely and completely independent of the ordinary light which the retina receives.

This was in the year 1843. I need not tell you that by the year 1845, in which year Mr. Claudet read another paper before this Society, further investigations by means of the spectrum had shown that Dr. Draper's idea was heretical, and at the present moment you know it is the general opinion of physicists, an opinion founded upon the work which has been done to advance photography and other researches since that time, that the radiations which you get from any light source, from the extreme violet to the extreme red, differ only in the rate and in the magnitude of the vibrations which are at work, so that I claim for the application of photography to spectroscopy, as a first result, the establishment of this great fact, that the visible, the chemical, and the heat rays are really part and parcel of the same thing, that thing being a system of undulations varying in rate and wave length from one end of the spectrum to the other, whether you consider the visible portion, or the invisible rays—those outside the blue, in one case, and outside the red in the other. But that is not all; I claim another thing for the application of photography to spectroscopy. Sir J. Herschel, so soon as he applied the prism, stated, in a communication to the Royal Society, that it was no longer possible to proceed with that branch of research under the best possible conditions, unless opticians would construct lenses which would bring the visible and the chemical rays into absolute coincidence. This is now done by our Rosses and Dallmeyers in the camera lenses, and that is the second great feature which I claim for the application of photography to spectroscopy.

## PRINTING FROM TWO NEGATIVES.—DENIER'S METHOD.

CONSIDERABLE interest has been felt by all who have seen the charming examples of softly defined portraiture—a few specimens of which were sent to the last exhibition of the Photographic Society by M. Denier, of St. Petersburg—as to the mode by which the roundness and singularly perfect modelling, the perfect definition without cutting sharpness, were obtained. Various rumours have been in circulation. Some maintained that the softness was the result of printing through a medium which prevented perfect contact between sensitive paper and negative, in the manner adopted by Carl Meinerth in his photo-mezzotints. Others, that a plate of ground glass was interposed between the lens and the sensitive plate in producing the negative. Others have suggested that a printing-frame similar to that introduced by Mr. Jacobi, in America, was employed; and others have suggested the use of two negatives. But as M. Denier sold his secret with conditions of secrecy, no certainty was obtained. A gentleman who recently visited St. Petersburg, and saw M. Denier and other photographers there, recently favoured us with a call, and from him we learn that in Russia the process has been patented, and that one of the licencees under the patent described the details. The process employed is, it seems, that originated and patented a couple of years ago in America, and since rediscovered in Italy, and consists in the use of two identical thin negatives, one of which being in contact with the paper gives sharpness of definition, whilst the other, superposed on the first, is, of course, separated by the thickness of the glass, and gives diffused definition, the blending of the two giving the happy compromise between fuzziness and extreme sharpness. There is sufficient of fine definition to do justice to delicate lines requiring crisp rendering; and sufficient softened or diffused definition to remove the crude, hard effect of excessive sharpness, which is sometimes offensive in its rendering of wrinkles, rugosities, freckles, and similar facial blemishes. A greater range of tones also becomes possible without risk of hardness. Starting with bare glass for the minute points of perfect blackness, and proceeding up to a degree of opacity which shall leave points of white paper for the highest lights, with all the possible intermediate gradations, gives us the highest quality of negative. But it not unfrequently happens that, starting from the same point, and continuing the intensification until opacity enough is obtained to secure absolute white in points of the highest lights, there is a tendency to bury detail and cause hardness. The less

intensifying a negative undergoes, as a rule, the more perfectly it retains all the delicate gradations of half-tone. Two thin negatives are, therefore, more likely to retain soft gradations than one intense one, whilst the combined opacity of the two thin negatives in the highest light will probably be quite equal to that of the one intense negative; so that the issue of the combination is the highest range of scale which the hardest negative can give, with an infinitely greater number of steps or gradations between the extremes of the scale.

The mode by which M. Denier obtains his two identical negatives did not transpire. Some difficulty exists in most of the methods employed. If taken in two sittings in immediate succession, there is risk of variety in expression and other minor points. If taken at the same moment on two halves of one plate, there is inevitably a slight difference in the angle. The method described by a Canadian amateur in our pages some time ago, in which both negatives are taken at one sitting by coating both sides of the plate with collodion, possesses many advantages. A process described by Signor Montagna in our pages might also be employed; but the paper negative from a paper print would lack some delicacy. The method we described recently, in which a duplicate negative is produced by the powder process, is probably the most promising method of any, as it secures to the photographer the greatest control over the quality of results. At any rate, there are various modes available for those who are anxious to try the experiment of producing soft and finely gradated prints like those of M. Denier.

## THE EFFECT OF VARIOUS KINDS OF ACIDS ON DEVELOPMENT.

At a recent meeting of the Photographic Section of the American Institute a discussion arose on the influence of different acids on the deposit produced by the developer. After some conversation,

Mr. Gardner said: I have adopted a practice different from anything I have ever heard of. A chemist told me that sulphuric acid was the best acid to unite with iron, and wherever I had to use iron I would find it to be the most useful. Upon that suggestion I took sulphuric acid and nitrate of potash in equal proportions, and then added a quantity of water, so as to make a stock solution, and to this stock solution I would add an equal quantity of alcohol, and this was added to the iron solution instead of acetic acid. I have used that, more or less, for eight years, and the best negatives and best ferrotypes I have made in my life I have made with that developer. I had the idea that the same thing might do, where they made the gun-cotton, to take the waste solution. I tried it, but I found it would not answer the purpose.

Mr. Anthony: I can bear testimony to the fineness of Mr. Gardner's ferrotypes; for they are certainly some of the finest I have ever seen.

Mr. Gardner: One other point. Acetic acid is very commonly used at the present time for washing the print when it comes from the printing-frame. I tried sulphuric acid for that. I took one ounce of sulphuric acid to sixty-four ounces of water, and that was the stock solution. Then I made the water acid with that stock solution, and put my pictures in that, and I doubt whether anybody could tell the difference between the action of acetic acid and sulphuric acid used in that way.

Mr. Chapman: Sulphuric acid will, no doubt, do no harm, only it reduces sensitiveness. I tried the experiment some time ago, taking different kinds of acids—citric, nitric, sulphuric, and acetic acid. I put a little silver in a bottle and added some iron. I took some of that, acidified with these acids, in test tubes, and examined the deposits. Nitric acid gives me the whitest deposit, and sulphuric acid gives the next, both of them apparently white metallic silver. The acetic acid gives a dark brown deposit. The same amount of deposit will make more opacity. Citric acid gives a dense black deposit. The best working deposit that is thrown down, for intensity, is the acetic acid. Some years ago we required vigorous negatives, but now we only want the detail, and supply the high lights with a pencil afterwards. No doubt you can get the same sensitiveness with a developer made from

acetic acid or from sulphuric acid, but you will get more detail with the same exposure from acetic acid. The use of these developers depends a good deal upon the question whether you are working for sensitiveness or fineness of results.

The President: The use of the acetate of soda has the effect of making a weak solution do the work of a strong one, by neutralizing the sulphuric acid and taking that out of the iron, so that you can use a much weaker solution of iron, and get more intense negatives. The ratio of the developer ought to correspond to the strength of the bath. A very strong developer and a weak bath will make thin negatives, because the ratio of the silver to the iron is small. The deposit of the image on the sensitive film is produced by the iron, and not by the silver. The deposit is thrown down according to the ratio between the two. If there is a large quantity of free nitrate of silver on the film, and the iron is weak, the image will be intense. If you have a fifty-grain bath, you can use a strong developer; if you use a thirty-grain bath and a twenty-five-grain developer, it will give a thin negative.

Mr. Anthony: My experience in the use of acetate of soda has been very favourable. Many years ago I had time to experiment, and obtained the best results in instantaneous exposure in using a small quantity of acetate of soda. At one time I kept on hand for toning an alkaline acetate of soda, and trying some of it in the developer one day, I found I got more detail and more rapidity of action than I could by the ordinary iron developer, and after that I always used it.

#### FRENCH CORRESPONDENCE.

Some days ago Nadar, the well-known Paris photographer, called the attention of the press to an experiment he was about to make. This was no other than an attempt at aerial photography, our friend being desirous of taking a photograph from the ear of a captive balloon at a certain distance from the earth, whence the panorama from below could be seen, a feat, by the way, which M. Nadar had already accomplished some years ago. It appears obvious that for strategic purposes in time of war, and for topographical purposes in time of peace, photography thus applied would render valuable assistance. Military science, which employed with advantage, in the campaigns of the first Republic, the corps of aeronauts formed by Courtelle and Conté, at the Ecole de Mendon, would be able to make good use of aerial photographs. Nadar believes fully that in surveying, also, aerial photographs will be of importance, and he is not the only one holding that opinion. A well-known engineer, M. Andrand, has also a similar idea, and he states that with photography to assist the surveyor, he would require no more theodolites, no more plane-tables, and none of the other elaborate paraphernalia which he is wont to employ; five hundred photographs, taken at a thousand hectares per day, would furnish a survey of the whole of France in twenty days.

It is not only in France that application is being made of our art in this connection; in Italy, also, they are busy doing the same. The skilful London optician, M. Negretti, if we remember rightly, made several practical experiments in this direction, but, so far as we are aware, M. Nadar is the only successful photographer who has been enabled, after numerous and laborious trials, to obtain in Paris, in 1866, a partial survey from the ear of a balloon. The photograph then secured is still exhibited in M. Nadar's studio in Paris.

To succeed in a work of this kind, it is necessary to have a very calm day, and apparatus suitable for the purpose. To prevent the movements of the balloon, the chief and only precaution to be taken is to have the machine sufficiently light that it keeps the ropes which fasten it to the earth straight and tight. There are still the gyrations of the balloon to be overcome, but these M. Nadar has prevented by a most simple arrangement. The instantaneous nature of his process, moreover, guarantees the success of his plates. I was only too happy to accept Nadar's invitation to be present during the experiment; but unfortunately, on the day in question, a storm took place, which rendered the ascent impracticable. We can only hope to be more successful another time.

M. Puttemans offers at the present moment to photographers a system of painting in oil colours, which may be practised, he assures all, without the operator possessing any previous artistic training. A workman, or even a child, may, he says in his circular, obtain satisfactory results. As I desired to learn something of the process, I not only visited M. Puttemans' exhibition of paintings which he has just opened, but I actually saw him at work with my own eyes, and can assure you that he does not exaggerate in his advertisement. Here is the process:—

The positive print upon paper, whatever may be its size, is in the first place rendered transparent by being immersed in a vessel containing a special preparation; it is withdrawn and attached, face downwards, upon a glass plate in such a way that it may be seen as a transparency. It is upon the back of the image that the painting takes place, so that the likeness cannot be altered, the design and modelling being both furnished by the photograph. Near at hand is a box containing a score of colours in oil, enclosed in tubes (perfectly similar to those which portrait painters employ), a palette of porcelain, a few brushes, and some bottles containing oil to dilute the colours, fixing liquid, and varnish. A little of the brownish-red colour is taken at the tip of a brush, and this is applied to the cheeks, lips, and shadows of the face. In this way several little patches are formed; then blue is applied in those places corresponding to the eyes, the outlines of the cheeks, and the half-shadows; then over the whole is applied a clear flesh tint. A tone more or less deep suffices for the hair and the beard, another tint for the coat, and another for the background. When the image is reversed after being thus coloured in a few minutes, one is quite astonished that all the tints have been so well blended, for they form quite a finished painting of some value, which, if it cannot be considered a *chef d'œuvre* in art, is certainly better than the portraits in oils which many photographers supply to the public. This is not all. When the painting is dry it is mounted upon linen, to which it is pressed or rolled in such a way that it forms one inseparable mass. Finally, it is varnished. I send you enclosed in the letter a specimen of this new method of painting, so that you may be enabled to judge for yourself of the results thus obtained. Personally, I think it is a method which will be found especially useful for the more humble or provincial photographer.

The meeting of the French Photographic Society, which was postponed until the 10th April by reason of the Easter holidays, did not furnish anything of particular interest. Nevertheless, we must mention that M. Thiel exhibited a series of photo-mechanical prints in greasy ink obtained by his photo-lithographic method, which is a modification of Albertype. The pictures were very fine, and possessed of remarkable delicacy, and bore comparison with the specimens of MM. Lomler and Jonas, who employ the Albertype process exclusively. The members present all admired the truly beautiful results, which rivalled the finest steel engravings.

The Academy of Sciences is busily occupied in making arrangements for observing the transit of Venus. In reference to this subject, M. Zenger has made known a method of enlarging photographs which he proposes to employ to amplify the pictures secured on that occasion. To obtain the image of the sun, he replaces the lenses with a mirror of long focus in such a way as to secure images of twenty-five to fifty millimetres in diameter. The spherical aberration is in this way rendered perfectly insignificant, and one need not trouble about the foetus of the chemical rays. It is proposed to correct the slight deformity afterwards by successive enlargements which will attain to a scale of 2,400 diameters. In this way one will be able to render apparent the craters, crevasses, and other invisible details in the original impression.

To resume, the plan of operating proposed by M. Zenger is as follows:—1. Observation of the passage of Venus at a given point of the disk of the sun in lieu of observing

contact on the sun's limb. 2. Instead of direct observation by photography, to employ a spherical mirror of long focus to obtain images as little as possible affected by spherical aberration. 3. Finally, the enlargement of the results obtained by successive operations, so that the amplifications may be on a very large scale.

ERNEST LACAN.

### AMERICAN CORRESPONDENCE.

#### THE ADVANTAGES OF THE BETTER EDUCATION OF PHOTOGRAPHERS.

*The Advantages of the Better Education of Photographers.*—Will you take kindly a few thoughts on this subject, since the commendable spirit of "reform" is rife among you at present?

At no period of our existence has there been such a revival in the cause of science as there is at present. Old men are dying, and leaving their millions for the establishment of institutes for technical instruction, and lectures are spreading such knowledge among the people in all directions. How good this is! And may photography share in it; for if ever there was a set of men who needed technical instruction in matters pertaining to their daily avocation, photographers certainly do now. How many of them are there who know why they are able to produce the results they do? and how many of them would know exactly what to do should any important obstruction occur in their manipulations? Photography is an infant yet, and we have not begun to see what there is in it, and we never will until some means are promulgated for the technical education of its votaries.

What we want, and what you want, and what every country wants, is a first-class college or school, where photographers may be thoroughly instructed in all the technicalities of their art. We are trying to get such an institution established here, and yet some of our silly people are opposed to it. Witness an example of the arguments given vent to by such an one. A correspondent writes:—

"I am much opposed to your photographic school. We have too many artists now; too much competition, and consequent low prices; and when our college opens up the same facilities for education as law, medicine, and dentistry do, your cheap fry will indeed be cut off, but sons of wealth will come in, and in great numbers, and their competition will ruin the business. Think over it. Pause. We should rather go slow, cautiously close the doors, and let none come in until he has served his two or three years' apprenticeship."

And this from a man who a few years ago was anxious to embark as a photographer, and whom—although I have never seen him—I literally taught photography by letter, until now he is one of the best workers in the State. For shame! Shall I apply to him the suggestion of Mr. Josh. Billings, that "some people forget when they were tadpoles"?

It is not to multiply photographers that we ask for a school for technical instruction in photography; but it is for the purpose of putting more science into those who are in, or may come into, our profession. A few weeks ago, at the anniversary of the Franklin Institute in this city, Prof. Morton, in commenting upon the immense advantages of aggressive science, said:—

"Example is better than precept, as the judicious copy-book used to say to us at school, and I will therefore take a ease and give you two views, the external or artistic, and the interior or scientific, of the same scene. We are in a valley among snow-capped mountains, and before us a lake spreads its mirror to the sky. No breath of air ripples its surface; no wavelet breaks upon its beach; nothing is there but absolute repose. So says the artist; and, painting such a scene, he calls his picture 'Silence,' 'Repose,' 'The Lake of Dreams,' or some such appropriate title.

"Now, however, let us look at that same scene with eye touched

by the wand of science, and opened to see beneath the surface of things. What do we then behold? Is there any longer an impression of repose, of rest, of sleep? Look at that mass of water, with its mirror-like surface. We see there a perfect Sebastopol of flying missiles. Water-atoms hurled in clouds from the surface into the air, water-atoms hurled back from the air into the water surface. It is by such action as this, science shows us, that evaporation takes place, or the invisible though rapid passage of the liquid water into the viewless air. The whole mass of the water is likewise thrilling through with those heat motions of which, if deprived partially, it would freeze into ice, and, if robbed utterly, would shrink into some formless horror, of which even the imagination of science can form no picture."

How truly is the photography of to-day represented by the placid lake as viewed through unscientific eyes, and how appropriately a picture of its condition might be called "Silence," or "Repose," or "The Lake of Dreams"! But this need not be so. Chemistry, and physics, and all the kindred sciences which call upon photography so often for help, stand ready to help us in turn (wand in hand) to see and to understand all that there is "beneath the surface." True, we should have some trouble to impress some of the hangers-on to our art of the importance of educating themselves. Let me illustrate. Another correspondent says:—

"I have been trying to get you a new subscription or two to send with my own, but have so far failed. The fact is, our people are very mean in some things. The majority would sooner have a dime novel than the choicest work on art or science, or rather attend a negro minstrel or Black Crook performance than a scientific lecture."

Alas! the city in which our correspondent lives is not singular in the propensities which he describes. It is hard to understand why it is that men who want to make a living and more, by their daily work, are so slow to employ all the means within their power to secure the desired end. But it has always been so—for ages, at least. "Palissy the Potter" spent years of diligent experiment in trying to discover the secret of glazing and enamelling chinaware, thus wasting the labour of a lifetime "in learning what the poorest Italian potter could have told him in five minutes." But instead of seeking for information at proper sources, first he plodded along his own way. How many photographers there are like him, who might be doing much better if they would but read. In commenting upon the "modern advantages" which the artisans of the present day have, especially in the way of literature, the *Public Ledger* says:—

"The point to be made in considering the subject is this: that every man, in whatever calling, in these days of scientific investigation and the printing press, should diligently read whatever pertains to his art, profession, handicraft, or pursuit. There are not a few who grope in the dark, like Palissy the Potter. He could not help it, but the modern artisan has no excuse. \* \* \* The ready writers who keep the printing press in motion are ever on the alert for subjects for their pens, and the man who reads and keeps himself up to the current of events and developments in any branch of human knowledge may find a short cut to the end which Palissy achieved in the journey of a life. He may even learn in 'five minutes' what it has required centuries to reveal. The man who does not read is far from appreciating the force of the question once asked by a 'self-made man': 'Does one need to know anything more than the twenty-four letters in order to learn everything else one wishes?'"

In a profession like ours, growing as it does far faster than its years would seem to allow, the followers of it should read everything published pertaining to it.

That puts me in mind of "a peace of poetry" recently sent me. I have not space for it all, even did the "peace" itself convince me that the author is well acquainted with the rules of versification; but I must give a verse or two, because of the wise admonitions which they contain, no doubt from a sincere and honest heart. He is writing about the value of photographic journals, and says: Had it not been for our journals,

"Where would our art have been to-day?  
I think that you will have to say:  
Drudging along at a fearful rate,  
In a dilapidating state.  
Let us open our pocket books,  
In the editor's eyes and look,  
We never can lose such a chance,  
*Here is the money in advance.*"

The last sentiment I like very much, and you, Mr. Editor, will endorse it.

One of the best educational means we have here is our National Photographic Association, and yet it has its opposition. For example, T. and H. say:—

"We are not members of the National Photographic Association, but hope to attend the Chicago exhibition. We perhaps are wrong in judging of the society by some of the members in our State, but their advancement of the art' has so disgusted us that we have not taken the interest we undoubtedly should in it." Another says:—"There are some things about the Association we do not like."

Now, let us ask these good people if there is anything in the world that is human that they find to be just as they want it? We should look at the good the Association does, and not at the evil transactions of a few of its members; make the highest progress our standard, our objective point, and not fault-finding with our neighbours. In addressing the Franklin Institute, a few weeks ago, our old instructor and contributor, Mr. Coleman Sellers, said:—

"Trust me, the teaching of man by man in frequent intercourse is the most potent means of acquiring knowledge, and knowledge well applied is indeed a power. Say not to me that learning unfits our men for work. I tell you proper instruction is what our working people most need—what the Franklin Institute has ever tried to give them. There is in the world drudgery to be done—drudgery that needs no brain-work—but there will be through all times enough stupidity to satisfy all the wants in this direction, and intelligent labourers will make their heads save their hands to their own profit, and the benefit of the whole human family."

"A word to the wise" &c. Until soon again,—Truly yours,  
EDWARD L. WILSON.

### ON COLOURING MATTERS SUITABLE FOR TINTING FILMS.

BY JOHN SPILLER, F.C.S.\*

THE practice of resorting to the use of colouring matters for overcoming certain defects in the operations of photography has of late years assumed much importance, and served a good purpose, particularly in connection with the emulsion and dry-plate processes. Without a due recognition of the value of a pigment or "backing," the early results on dry plates were subject to the disadvantage of halation, arising from the blurring of the image on the collodion film by the secondary reflections from the posterior surface of the glass plate at the moment of its being exposed in the camera. These defects are chiefly observed when the preservatives employed are those which determine an unusual degree of transparency in the film; and with wet plates the same consequences follow the use of lightly salted collodions. For a time burnt sienna mixed with gum and glycerine was universally resorted to as a pigment for backing the plates, and correcting this tendency to abnormal reflections, but latterly this has given way to an adiacinic varnish, blackened paper, or carbon tissue at back, or a colouring matter applied sometimes to the face of the plate. Mr. Henry Cooper, Mr. R. Manners Gordon, and Colonel Stuart Wortley have worked in this direction, and advocated the system of tinting or staining the film, their experiences being recorded in the YEAR-BOOKS; Mr. Weige has likewise turned his attention to tinted transparencies; and Dr. Hermann Vogel claims to have discovered an important and hitherto unsuspected function in the possibility of rendering bromide of silver

sensitive to the so-called non-actinic rays, through the agency of aniline green and other coal-tar colours applied to the film as a supplementary wash. The whole subject is therefore one well worthy of investigation, and I need no apology for bringing the dyes themselves under your notice this evening, with such brief remarks and experiences as I am enabled to give at the present time, chiefly from a chemical point of view.

My list of colouring matters includes rosaniline and its salts, crysanilino or phosphine yellow, aurine, Hofmann's violet, iodine green, and aniline blues of different qualities, prepared by Girard's and Nicholson's processes. We have thus a range of colours diversified almost as the solar spectrum, and capable of employment either directly as tinctorial agents, or serving more recondit physical purposes in screening back certain rays which otherwise would have their influence, in ordinary daylight, during exposure. The optical quality of the colours may be accurately determined by looking through the solution with a prism or spectroscope, and the area of absorption is at once apparent for all the visible rays. The reds and yellows cut off the most active and highly refrangible rays, so that on this account they are employed by preference as antidotes in stopping halation with the dry plate process. Of these colours I now proceed to give a more detailed description.

*Rosaniline (rosine or magenta).*—The salts of this base most frequently met with in commerce are the hydrochlorate and acetate, both being freely soluble in water. When a cold aqueous solution is required, the acetate should be used. This can be procured in crystals or in the form of rosine cake—a fused mass of cantharides or brassy metallic lustre. Its tinctorial power is very considerable, so that a grain or two will redden a pint of collodion or dye an ounce skein of wool. When the hydrochlorate of rosaniline is mixed in solution with nitrate of silver, a pale pink precipitate is formed, consisting of chloride of silver in intimate combination with the rosaniline. This is very rapidly affected by light, for the organic base aids in the reduction of the silver salt, and appears to absorb the chlorine liberated. The life-sized heads shown at the last exhibition by Colonel Stuart Wortley were, no doubt, examples of tinted photographs produced by immersion of the finished prints in a weak solution of rosaniline. If their colour be deemed too strongly marked, it is easy to moderate the action by the use of a more diluted solution; but the character and effect produced may be judged from the pictures. A short notice of this and other applications of magenta appeared in the YEAR-BOOK OF PHOTOGRAPHY for 1869 (p. 38), and as one of the "Practical Suggestions," I pointed attention to the possibility of imparting a warmer colour to over-toned proofs in this manner. Mr. Henry Cooper has recently described a mode of using rosaniline in collodion which is said to be without any detrimental effect upon the bath—in consequence, doubtless, of the before-mentioned affinity for the silver iodide, if not for the pyroxyline itself.

*Crysanilino (phosphine yellow).*—This body occurs in commerce in the form of a deep orange powder, which is freely soluble in hot water. It likewise combines with chloride of silver, giving it a yellow tinge, and an aqueous solution of phosphine stains the collodion film of the same colour. Alcoholic solutions may be employed in cases where water cannot be used. Albumen is easily tinted by it, but the colour is not one that would be desired.

*Aurine* is met with in the form of a resinous cake which is quite insoluble in water, but is taken up by ammonia, forming a deep rose-coloured solution which does not dye well. It is freely soluble in warm alcohol, and by admixture with a little shellac gives a very good non-actinic varnish of permanent character. Mr. R. M. Gordon has used aurine in collodion, and reported very highly of it as an agent for preventing halation. Used as a dye upon silk the colour is a magnificent golden yellow; it has no affinity for cotton, but with certain mordants gives a bright scarlet on wool.

*Hofmann's violet (ethylated rosaniline).*—This colour may

\* Read before the South London Photographic Society.

be had in several shades, varying from the reddest violet to purple. In general properties it closely resembles rosaniline, and is freely soluble in alcohol and water, the solution staining collodion, albumen, and animal fibres. Examined by the spectroscope, it appears to be transparent to all the upper visible rays, but, nevertheless, somewhat impedes the action of light in the camera.

*Aniline green (colic green).*—The latter name, by which it is commonly known, has been conferred upon it in consequence of its containing iodine as a necessary element. This, driven out by heat, destroys the compound, with reproduction of the original violet from which it is made by Hofmann's process. The aqueous solution cannot be boiled without injury to the colour; but a warm infusion serves to dye collodion or silk, and reference has been made to Dr. Vogel's recent experiments with this colour. It is freely soluble in alcohol, and may be obtained in splendid crystals of a dark bronze appearance. It is generally met with in the form of a dark green powder, which contains a little common salt, used in separating the colour from admixtures of violet.

*Aniline blue (phenylated rosaniline)*—"Bleu de Lyon" was first prepared by Girard, by the action of aniline upon magenta or aniline red. This body is not soluble in water, but becomes so by treatment with oil of vitriol, according to Nicholson's process. Many improvements have been introduced by which the colour is fitted for various purposes. Opal blue is used for dyeing silk of the finest shades; Nicholson blue goes well upon wool; and soluble blue is used for cotton. The first of these is, like the "bleu de Lyon," quite insoluble in water, but is taken up by warm alcohol, forming a magnificent blue solution, which cuts off all the yellow, and much of the lower portion of the spectrum. Nicholson blue is an alkaline preparation, freely soluble in water, but of minor interest for our present purposes, since it requires an acid for development. The soluble blue is prepared of several qualities, and one of this series—named China blue—has been made the subject of experiment, by Mr. William Brooks and myself, for tinting films of a bright blue colour. The aqueous solution dries to a structureless mass, which led me to try its employment as a preservative in the collodion process. My first attempts were made last summer with solutions of unknown strength; but Mr. Brooks has recently gone over the same ground in a more exact manner, using solutions containing respectively twenty and forty grains per ounce of water, and applying directly to the washed sensitized plate (bromo-iodized collodion), washing off the excess of dye in some instances, and at other times leaving it on to dry. In every case the exposure had to be very considerably prolonged, in order to get fair negatives with a gelatino-iron developer, and there was a difficulty in seeing through the plate for the purpose of watching the development. Methylated spirit afterwards removed the blue from the film; but if left in, this colour did not offer any practical obstruction in the printing. Working with three and five-grain solutions of the China blue, the diminution in sensitiveness was very marked, so that there is little prospect of being able to take advantage of this neutral blue in the preparation of dry plates, unless, indeed, a retarding influence, in special cases—as in photographing the sun—is particularly desired.

#### LIGHTING AND VENTILATING THE DARK ROOM.

DEAR SIR,—Resuming the subject of lighting the dark room, to which I devoted some attention in your columns a few months ago, it is necessary to consider the essential conditions required, and how and by what means to obtain them. I feel sure it will be acknowledged that there should not only be enough light to enable all who possess an ordinary degree of vision to be able to perform any operations required clearly and without straining the sight; but that also the quantity should be sufficient to prevent the too

frequent violent action upon the nerve of the eye, caused by sudden transitions from light to darkness, and the contrary, on entering or leaving the dark room—certain to be injurious to all, and in many cases causing incurable blindness. The light should proceed from one source, and flow in an evenly diffused sheet over that space which is required by the operator for his labour. Should there be a window at a distant part of the room, lighting that portion only, it will not be objectionable, as it can be darkened when required. The method of obtaining non-actinic light should in no wise permanently obstruct ventilation. I believe that no perfect separation of the three powers of the sunbeam can be made; therefore we must be content if we obtain a light that will remain innocuous during a reasonable space of time—say sufficient either to prepare or develop the most sensitive plate. It should be free from sudden transitions, therefore the sun must at no time be allowed to shine in at the window, even in preference to white light. Could it be obtained free from actinism, it would be better that it should be of some soft, neutral tint, avoiding all vivid colours, especially red, which irritates and inflames the nerve of the eye, even sometimes causing such a general irritation of the brain as to produce fever.

I do not know whether it has ever been taken into due consideration, but in the use of coloured light there is a point which, if overstepped, what is gained in non-actinic power is more than counterbalanced by the great loss of light incurred. The best method of lighting the dark room is by hanging a sash containing coloured glass inside an ordinary window, thus allowing both to be opened, and white light admitted when required.

Various means have been tried for the purpose of producing non-actinic light. Coloured fabric, such as silks and cotton, have been used both in the form of blinds and curtains. All are objectionable. Fabrics of any sort are liable to be torn, to become faded, stained, and dirty, and after washing, the stiffening being thus taken out, may become little better than fine sieves, through the meshes of which a large quantity of white light is allowed to pass. Curtains, from their folds being of unequal density, will be apt to throw streaks of different degrees of light upon the work in hand, and are in many other ways troublesome and not to be depended upon.

Feeling assured that the subject now under consideration is of the greatest importance to photographers, not only as regards the beauty of their work, but also for their comfort and health, I have wished to make this dissertation as comprehensive and as practical as in my power. I have with this view made some experiments with samples of various coloured glass, talc, and lantern horn, and have formed a comparative table of their properties as regards light and actinism, from which I glean the following results:—

Talc may be said to be about equal to a bad specimen of common glass; its laminae being very apt to scale, and it not being capable of being coloured, it is useless. Lantern horn, being light, strong, and capable of being dyed, would, I consider, prove very useful for glazing developing boxes and those containing sensitive dry plates which have to pass through foreign custom-houses. I find, also, that the use of orange glass is a mistake; its colour is produced by a mixture of glass of antimony and red lead; it stops out a much greater portion of light than actinism, and admits heat. The colour of red glass is obtained from copper. As it depends it possesses the above obnoxious qualities in increasing proportion. Yellow glass, the colour of which is obtained from silver, appears to be above all other the best adapted for lighting the dark room. It freely admits light, and strongly resists actinism. When more than one layer is used, the united colour is a muddled yellow, and not orange. Even three thicknesses of yellow will admit more light than one of orange glass, and, of course, stop out a far greater proportion of actinism. I should therefore consider that two layers of yellow glass of a moderate thickness, which might be supplemented by one of a light blue colour, to make the light less injurious to the eye, would prove all that could be desired. It may here be noticed that actinic rays being once obstructed, no additional medium of any colour whatever will do away with the obstruction and enable them to pass.

I do not feel it necessary to bring under examination the relative power of other colours, and leave it to your decision whether you consider the tabular list I have formed of them is of sufficient interest to be placed before your readers.—Yours truly,

JAMES MARTIN.

#### ENAMEL PHOTOGRAPHY.

DEAR SIR,—In your last issue I notice a copy of a communication from Mr. J. J. Atkinson, of Liverpool, to the American paper, *Anthony's Bulletin*, respecting enamel photographs; and I simply wish, in writing this, to enter my protest against that gentleman,

or any one else, stock dealer or otherwise, who thus coolly appropriates and makes use of for trade purposes a copy (often using my own words) of part of my enamel method, for the sale of which he was agent some four years ago.

If your extract be correct, Mr. A. sends this process apparently as the best one he has discovered, and makes not the slightest allusion to the name of the inventor. The moral conscientiousness of these sort of people must be very large.—Yours truly,

W. T. WATSON.

[The inventor of the process in question was Herr Grune or M. Tessie du Motay; we do not at this moment remember which published first. But they both patented the method of producing enamels by converting the image of silver into an image of the noble metals, such as gold, platinum, palladium, iridium, &c., either alone or in combination with each other, or of the oxides of other metals capable of vitrification when fired with a flux. Some attempts of the same kind, but less systematic, had been made in this country before by Mr. Barnes and others. Since the publication of the methods of Grune and Tessie du Motay, various modifications and improvements in formulae have been devised by different photographers, the aim and result of which have been greater excellence and certainty in result. It is probably to an improvement in formula that Mr. Watson refers as an invention. We have understood that his formula has in some hands produced very good results, and we have seen some of his enamels which were very good; but surely he is not so imprudent, whilst selling a secret method, as to identify it with any published formula.—ED.]

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

A MEETING of this society was held on Tuesday, the 14th inst., of which a full account will appear next week.

Mr. GLAISHER stated that before taking the chair he desired to know whether it was the unanimous wish of the meeting that he should return as president under the conditions notified to the acting secretary, viz., that he and the members of council who had resigned should be returned temporarily as *the council* of the society until a new code of laws had been passed? He had resolved, when he left the chair, never to return to it again; but at the earnest solicitations of many friends, and much against his will, he had consented to do so.

On a show of hands being taken, no one voted against the return of the president and council to office.

Mr. SORWITZ, M.A., F.R.S., congratulated the members on the favourable turn matters had taken.

Mr. HUGHES desired to know whether the six gentlemen elected on the council at the annual meeting did not form part of the present council, just as much as the older members of council?

Mr. GLAISHER, in reply, said that the only conditions under which he could take office again, until the new laws had been passed, were those he had stated. Although he esteemed the six gentlemen highly, he could not consent to act with them. The former council had had a slur cast upon them by the manner in which they had been treated, and by the non-election of not a single one of their nominees. Under these circumstances he could not take the chair.

Mr. Glaisher then retired, and Lord Lindsay, Mr. White, and the Secretary also gave in their resignations.

Mr. SPILLER was called to the chair, and after some further discussion the minutes were read, and subsequently confirmed.

Mr. PRITCHARD, on behalf of Mr. Bruce, read that gentleman's paper "On the Printing and Toning of Collodio-Chloride Paper," and exhibited to the members specimens of Mr. Bruce's work. After a long discussion, and a vote of thanks to Mr. Bruce, the meeting was adjourned to Tuesday, May 12th, a special meeting to be called in the interim to consider the present condition of the society.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this society was held on the 9th inst., the Rev. F. F. Statham, M.A., president, in the chair. After the reading of the minutes of the previous meeting,

Mr. SPILLER read a paper "On Colouring Matters Suitable for Tinting Films," (see p. 189).

Specimens of the various colouring matters, and of the fabrics and collodion films dyed with them, were exhibited. The effect of heat upon iodine green, in changing the colour to violet, was likewise shown.

The CHAIRMAN considered that the subject was one of great importance. Referring to the experiment of Dr. Vogel, he inquired if the same effect of practically increasing  $\frac{1}{2}$  the sensitiveness of the yellow rays could not be produced by the interposition of a coloured film in front of the sensitive plate?

Mr. SPILLER thought that when the colouring matter was in contact with the chemicals a different effect would be produced than when it was applied in the way indicated by the Chairman.

Mr. BROOKS had experimented with blue films. He first of all exposed a wet collodion plate to ascertain the exact time required, and he then gave exactly double of that exposure to a blue stained film, but could not develop a visible image. On attempting to clear the film with cyanide of potassium a very faint positive image appeared, and this experiment was repeated with the same result. He thought that aniline might possibly be used as a restraining agent.

Mr. SPILLER observed that cyanide had a curious effect upon a coloured film. He then showed the effect that heat had upon a sheet of paper that had been dyed with iodine green by moving a lighted match underneath it. The heat converted the green into an intensely deep violet.

Mr. FOXLEE threw out as a suggestion the use that might be made of the iodine green as a means of avoiding halation. As heat caused the green colour to be converted into violet, a film that contained a little of the iodine green would, from its colour, give freedom from halation, and after the negative was developed and finished, the application of heat would convert the green into violet, which would not interfere with the printing.

Mr. HOWARD exhibited several transparencies that had been tinted of a warm colour by means of aniline. Two pictures of a similar kind were shown, one of which had received a wash of aniline, the other being left intact. The former was rich and warm compared with the latter. Mr. Howard observed that it was easy to produce warm tones when operating upon dry plates; but what was desirable was the production of such tones upon a wet collodion plate that had been developed with iron in the usual manner.

Mr. BRIDGE spoke of the desirability of interposing the coloured films when printing.

In reply to a suggestion by Mr. BROOKS relative to the possibility of applying aniline dyes for colouring transparencies,

Mr. TAYLOR observed that complete sets of aniline colours had been prepared for this purpose. Several years ago he had purchased aniline dyes adapted for transparency painting.

Mr. HOWARD, in reply to a question, described the method he adopted for removing the backgrounds from his negatives by means of iodine. He cut a piece of blotting paper to the size required, moistened it with tincture of iodine, and then applied it carefully to the negative. This prevented the iodine from spreading. He finally applied a wash of cyanide of potassium.

In reply to a question by Mr. FOXLEE concerning the effect of aniline upon the permanence of silver prints,

Mr. SPILLER said that this had not yet been ascertained. With respect to the dye itself, it was bleached by the action of light.

The thanks of the society were awarded Mr. Spiller for his communication, and specimens of some of the aniline colours were distributed among the members.

The meeting then adjourned.

## Talk in the Studio.

IMPROVED PHOTO-LITHOGRAPHIC TRANSFERS.—Somewhat more than twelve months ago we described, in the PHOTOGRAPHIC NEWS, an improvement in photo-lithographic transfers, originated by Mr. Walter Paul, who found the substitution of albumen or gelatine gave greater crispness to fine lines. We have been not a little amused to notice the migrations of our announcement. The facts of Mr. Paul's improvement were quoted in a French journal without any allusion to the authority from whence the information was derived. The paragraph then travelled through various continental journals, and thence back to this country, the originator of the improvement having in the meantime had his nationality changed, and the discovery became that of a Frenchman. It has now reached America, and in the last number of *Anthony's Bulletin* we are informed that "M. Paul, in the *Journal Les Mondes*, describes an improvement," &c., giving details of the modification.

KING COFFEE'S UMBRELLA.—The Royal state umbrella of the King of Ashantee, brought over as a trophy from Coomassie, and presented to her Majesty the Queen, has been photographed at Windsor Castle by Mr. Adolphe Beau, of Regent

Street. As a distinguishing character of the object is in its being made of alternate squares of crimson and black velvet, the photographs have been coloured, to show this peculiarity, with proper effect.—*Telegraph*.

**STEALING PHOTOGRAPHS.**—Richard Turnbull, reported in our last as charged with stealing photographic goods from Mr. G. Taylor, was sentenced on Friday last to eighteen months with hard labour.

**A NEW TEST FOR AMMONIA.**—Almost every month our exchanges announce the discovery of some new test for the volatile alkali, whose presence, when free and in large quantities, is so readily detected by reddened litmus or by the human nose. In recording each new discovery we leave it for our readers to decide which will be in any case the most convenient for their use. The reagent employed by Moddormann is simply a solution of blue vitriol or copper sulphate. When this salt is dissolved in pure water a clear solution is the result, but the addition of a trace of ammonia causes a greenish precipitate, especially if warmed. So delicate is this reaction that ammonia may be detected in distilled water if a large quantity of the latter be employed. The precipitate is basic sulphate of copper.—*Journal of Applied Chemistry*.

**LOOK AT THE OBJECT.**—Endeavour to have the object at which the sitter is to look of the proper size, and the right distance off. A dark whole-plate photograph is as good as anything.—*Photographer's Friend*.

## To Correspondents.

**ANSWERS BY POST.**—We have often explained that it is impossible for us to answer questions of correspondents on photographic subjects by private letter. Nevertheless we are every week asked to write many such letters, and are compelled to assume the apparent discourtesy of declining. With every wish to oblige all our correspondents, it is utterly impossible to undertake other than Editorial duties on their behalf. Our time is already very fully occupied with journalistic duties, leaving us sadly too little leisure for other matters which have special claims upon us; but were we to undertake answering correspondents on photographic difficulties by post, and to undertake various commissions we are frequently requested to look after, from one to two days in every week of our time would be fully occupied in such matters alone. We hope several correspondents this week, as well as on other occasions, will accept this intimation.

**E. S. J. II.**—We have no means of knowing the precise quality of the beer which Captain Abney used in his Beer Process described in the *YEAR-BOOK*. It is probable it was drawn from the barrel in his cellar for home supply, and is the production of some brewery at Chatham or Rochester; or possibly it was obtained from the canteen at Chatham. It is probable that the beer was not porter, but pale ale, which in London is commonly, as you probably know, spoken of as "bitter," or "bitter beer," or "beer," although at one time, and in some circles, we believe, porter was commonly spoken of as beer. The possible adulterations might have an injurious effect, but the exceedingly minute proportions in which they would probably be present, when present at all, would reduce the risk to a minimum. Salt, as you know, is used in some processes to get rid of free nitrate, and the minute traces of chloride of silver formed would probably be at least innocent. Sulphate of iron has been employed to give increased rapidity; but its presence might be more injurious than the other possible adulterations. Irish moss, tobacco, &c., in infinitesimal quantities, would not be likely to be injurious. In trying the process, use any ale at hand.

**J. H. C.**—If you look through the *YEAR-BOOK* for the last few years, you will find several tests for the presence of hypo described in detail: Grune's test is a very good one. It consists in preparing a collodion plate, exciting, exposing to diffused light, developing, fixing, washing, &c., and then treating with a ten-grain solution of bichloride of mercury until whitened. A portion of this film moistened with water supposed to contain hypo will darken if very minute traces of hypo indeed are present. Perhaps none is better than the iodide of starch test, which you will find in the *YEAR-BOOK* of a few years back, described by Mr. Spiller. As we write at a distance from home, we have not the means of referring you to the precise year at hand.

**TAMMY.**—Tammy is a woollen material which may be obtained of most drapers or upholsterers. It is used chiefly for the purposes of the dhalsterer.

**P. C. W. (March).**—Any cloth which is impervious to actinic light will answer for a tent. The object of using yellow calico is to get rid of white or actinic light without quite getting rid of illumination.

**ENQUIRER.**—We fear that the lighting facilities you describe are not very good. In the first place, eight feet to the eaves and eleven feet to ridge will give you an insufficient angle even to throw off water. If it can be done, make the height at eaves not more than six feet. You require no light at either end; and, with a good skylight on the north side of such a pitch as we have mentioned, you can well dispense with top-light or side-light on south side. The north skylight, if only six feet square, might serve in fine weather; but in dull weather it would, we fear, be found insufficient. You should, undoubtedly, have side-light as well as top-light on the north side. The south light might be useful in winter, but very troublesome to work in summer.

**J. P. (Canterbury).**—Thanks for sight of the cutting; the writer was clearly all abroad on the subject. In our estimation, the card portraits with landscape backgrounds were the finest ever issued. Other photographers have sent out fine work of that kind; but no one has ever used such a speciality of this class of work as Mr. Edge. The subdued, misty effect of the landscape, which gave such force to the figure, was obtained by printing upon the grey ground obtained from a light background screen in the studio, instead of a pure white ground, which was used by the firm you name. The method of double printing they adopted had been used by Mr. H. Robinson's brother many years before. A method proposed by Mr. Burgess, of printing a background on the negative with collodion-chloride, was very effective. Thanks; we shall publish the method of mounting shortly. The risk to which we referred arises from the print being mounted on the glass, and, in case of breakage of the glass, involving destruction of the print; whilst an ordinarily glazed picture is not necessarily injured if the glass break.

**A. G. W.**—Your negative arrived quite smashed. A negative should be packed in a wooden box sufficiently strong to resist the blow it may receive in stamping, and the careless usage in transit. If you send us a print from one of the negatives we can probably aid you. The defect may arise from many causes. It may be bad lighting, it may be under-exposure, it may be the fault of the chemicals, it may be insufficient development, or some other cause which, on seeing a print or negative, we can probably explain; and we shall have pleasure in helping you.

**PINS.**—We have repeatedly described the method of enamelling prints, both in the *NEWS* and *YEAR-BOOK*. It would occupy too much space to be repeated in this column. You will find it in our last *YEAR-BOOK*, in an article by Mr. B. J. Edwards.

**BEE-HIVE.**—As different samples of chloride of gold contain different proportions of free acid, it is impossible to say how much lime water will be required to neutralize samples generally. Add a little at a time, and test with blue litmus paper, giving a little time between each addition to allow the re-action to be completed before testing and adding more lime water.

**ARCHER CLARKE.**—The law of copyright in engraving extends through two or three Acts of Parliament, and as we write from home, and have no access to authorities, we cannot answer with certainty. In any case, you had better send us a copy of the prints and of the publication line, to enable us to judge of the probable conformity to the law. We hope very shortly to make use of the information you sent us some time ago, and will then return the documents. Thanks for sight of them.

**ONE IN TROUBLE.**—The matt silver markings of which you complain come from a variety of causes; but where plates have worked clean all day, and the stains only begin to appear towards the close, the causes must be limited, and easily traceable. In the first place, the inner frames have probably become saturated with silver solution, and are not quite clean, although you think they are. Try having extra inner-frames, dry and clean. Be sure to allow the plate to rest upon clean blotting-paper. Again, as the day gets warmer the plates dry more quickly; immerse the plate before it is so thoroughly set. Possibly, after a hard day's work your bath gets over-charged with ether, &c. Try having an extra bath.

**OXONIENSIS.**—We have tried Forrest's patent plate substitute with much success and satisfaction. 2. The best method of dealing with refractory plates which resist ordinary cleaning methods is to use putty powder, as described in our last *YEAR-BOOK*. It really cuts away the dirty surface, and gives a clean newly-polished surface. 3. Old collodion is very good for cleaning plates, but very unpleasant, especially to the eyes.

**D. U. T.**—Intensifying with iodine answers very well when just a little additional intensity is required. It is important not to apply the iodine solution too long, or, as you say, it turns the whole film yellow, and causes flatness. Just flow the surface for a few seconds with a weak solution, say one grain iodine, two grains iodide of potassium, and one ounce water. The colour will become olive, giving to the highest lights density. Wash off quickly. But if you wish to increase the intensity, more pyro and silver, or iron and silver according to any of the recognized formulæ will answer best.

**LEO.**—Thanks. In our next.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### POISONS IN THE STUDIO—THE SCIENTIFIC CLUB—THE BANE OF RETOUCHING.

*Poisons in the Studio.*—One ought always to profit by experience. Photographers are well aware of the poisonous nature of most of the chemicals with which they have to deal, but any further information on the point is always acceptable. The deadly effect of cyanide of potassium is universally known, as also the fact that one of the best antidotes for it is iron, so that in the case of a patient having swallowed a dose of the fixing agent, relief may at once be secured if he will only follow up the matter by taking the developer. In this way ferrocyanide of potassium, or Prussian blue, a comparatively harmless body, is formed. Again, in the case of bichloride of mercury or corrosive sublimate, much used in some studios for intensifying, the photographer who possesses the poison has usually the antidote also: white of egg, or albumen, swallowed after a dose of corrosive sublimate has the effect of combining with the same and producing an insoluble mass. Pyrogallie acid is said to be a most violent and horrible poison, in its effects very much like other deadly organic bodies, such as aconite, strychnine, &c. Alcoholic poisoning is, unfortunately, not very rare, and its symptoms are well known by medical men; but the effect of ether upon the system is a subject which still requires study. Of the influence of bichromate of potash, in solution, upon the system, we were recently told something in the American papers, some actors who were performing the drama of "Ten Nights in a Bar Room" having swallowed some of the liquid by mistake. The stage manager employed some coloured water, tinted with bichromate of potash, to represent whiskey in one of the drinking scenes, and two actors who partook of the liquor were immediately seized with convulsions, not recovering from the baneful effects until some days after. Bichromate of potash would exert a corrosive action rather than a poisonous one upon the coats of the stomach, and it would be difficult, we think, to suggest an antidote; the best course, probably, to be pursued under the circumstances being to give an emetic and to use the stomach pump as rapidly as possible. It would be well, indeed, for photographers always to keep an emetic in a conspicuous place in their studios ready to hand, in case of any mistake, for loss of time is always dangerous in cases of poisoning: a solution of sulphate of zinc will be found a capital emetic under general circumstances.

*The Scientific Club.*—The Scientific Club appears now to have become an established fact, the number of foundation members, amounting to two hundred and fifty, having been obtained, and rooms are now being fitted up for the reception of members. For the next two hundred and fifty members the entrance fee will be two guineas, and subscription three guineas for town, and a guinea-and-a-half for country members. We see there are several members of the Photographic Society belonging to the club, and there are two, Lord Lindsay and Lord de Blaquiere, on the executive committee, so that photographers may be said to be well represented. The rooms now taken are only secured temporarily until the limits of the club can be properly estimated, but the site will be adjacent to Burlington House, and, therefore, in close proximity to the meeting rooms of most scientific societies. It is strange that scientific interests should not have been represented before in the shape of a club, for neither the grand Athenæum, nor the cosy little Savile, although much frequented by scientific men, can be called scientific clubs, as they receive their main support from votaries of literature and the arts. And this is the case also with the Savage, Whitefriars, and other social clubs.

*The Bane of Retouching.*—Says Miss Thackeray, in her charming book of "Toilers and Spinsters":—"A photograph of your friend will, to a certain point, tell you more about him in one minute than whole pages of elaborate description. You see him himself: the identity is there—the dull, worn look, or the familiar cross-grained expression, or the humorous twinkle of the eye, or the little vanities or negligences of dress which always belonged to him—they are all before you, summed up upon a little bit of card which tumbles out of his letter." The services photography renders to families and loving friends could not be more graphically summed up than we here find it. One cares little about the high class or finished character of a photograph; so long as the picture before us is a photograph of our friend—may-be of one for ever lost to us—we have nothing else to wish for. The print may be harsh, ill-toned, badly-lighted, and of an unpleasant colour; all this is nothing compared to the assurance that it was taken from life. It has often been said that at the present day we should be glad to exchange any number of marble busts or grandly painted portraits of Shakespeare for one little brown photograph of the gifted genius. How we should all study the wrinkles on his forehead, and the care-worn lines upon his cheeks! How we should try to gather something of his pathos out of his gentle eyes; or endeavour to seek a trace of humour in the lines of his mouth! We should not have blessed the art of retouching had it been much in favour in the time of good Queen Bess, and had smoothed down every line or mark upon his visage; and this photographers who are so handy with their pencil now-a-days should remember. If we have a photographic portrait before us in which the lines and expression of the face are unaltered, and the face is as it was reflected by the original into the camera, we have a more truthful representation than the most skilled artist in marble or colours can produce, and one, too, which will always find admirers to the end of time. We may endeavour to secure as truthful a reflection, and as agreeable a reflection, as we can, and strive to let none of the most minute details be wanting on our plates; but do not let us leave out or modify any natural lines, however unseemly or unpleasant they may be.

### ON PRINTING AND TONING COLLODIO-CHLORIDE PAPER.

BY GEORGE BRUCE, OF DUNSE.\*

I HAVE been invited by your courteous secretary to write a short article describing the material and means used by me in printing and toning the pictures I had the honour of sending to the society's annual exhibition last year. I had some difficulty in making up my mind to accede to Mr. Baden Pritchard's request, not because I wished to keep to myself knowledge which others might not be possessed of, but because I was under the impression that the members of the society knew as much as I did on the subject. Having, however, given a promise, I now proceed to redeem it, to the best of my ability, by writing a short paper explaining my method of printing and toning collodio-chloride paper; and I only hope that something may be said that will induce the members of our profession to take a deeper interest in a process which, somehow or other, in this country, the place of its birth, has never gained that practical footing it so well deserves.

Before detailing my plan of working, permit me to express my ideas upon the subject of artistic tone, in its wider sense, as representing not only colour or tint in the photograph, but as embracing richness, depth, and delicacy of gradation in the negative also. And here I may say, in regard to tone or tint, in the usual acceptation of the term, I expected, in the event of any notice being taken of the photographs which I sent to London, that objections would be raised to their tone, as being too

\* Read before the Photographic Society of London.

cold or black. The reason I had for expecting this adverse criticism was, that the majority of photographers with whom I have spoken on the subject consider brown tones the most suitable for photographic prints; and, further, the work produced and sent out by the profession generally indicates a leaning to what are popularly called "warm tones."

Under these circumstances, I was agreeably surprised to find that my pictures were favourably mentioned on account of their colour. My own feelings for some years have been in favour of black colours, as better fitted to display the delicacy of gradation found in a negative; and consequently I have done everything I could to produce in my work the purple black, as well as the transparency of a first-class engraving, being convinced that the nearer I attained to these two qualities the more artistic would be my pictures.

My predilection in favour of this tone rests upon the fact, in the first place, that the artistic world, both in the past and present century, have adopted a blue-black ink upon a white ground as the most effective and pleasing tint for pictures in monochrome. They were perfectly well aware (as we are ourselves) that neither a brown nor a black ink could represent colour as seen in a painting; but between the two they chose the latter as the best medium through which to show the wonderful power of the artist engraver in rendering the semi-transparency of flesh and texture of fabric by the skilful use of light and shade alone.

The second reason I give for preferring a black to a brown tone is, that I believe the delicate shadows which lie just beneath the highest lights of the picture receive more beauty and value when the photograph is toned deeply than if the toning had been stopped at an earlier stage. The gamut or scale of gradation at our command is more limited than that of the painter, and we require, therefore, to husband our resources all the more carefully, so as to make each degree of gradation tell in our finished work; and if we can extend—or, at least, make more visible—these gradations by toning past the brown to a rich black, then by all means let us do so, as the essential spirit of a photograph lies in its pearly half-tones.

As we listen to such a man as Signor Foli, in his song of "The Diver," we are conscious of a feeling of wonder and awe as the artist carries us down with him into the "waste of waters." Again, when Mdlle. Tjitjens renders, with all the force of her magnificent voice, one of those airs in which the composer lends brilliancy and weird-like power to the composition by using the higher notes of the scale, our ear, while entranced and thrilled with the music, feels sometimes strained and excited with the pitch; but let the same lady sing the simple "Home, Sweet Home," with its gentle undulating tones falling sweetly on the ear, and our hearts are at once touched by the more soothing and natural melody.

So is it in looking upon beautiful paintings, engravings, or photographs. Without the middle tints we may have a bold, clear, glaring picture, with its startling effects of strong contrast, but of which the eye soon grows weary, though it may have been arrested for a moment; while, with the addition of a cool grey tone, filling up the picture between the highest lights and deepest shadows, modelling and transparency are at once imparted to the whole, and a picture full of tenderness and beauty is the result. While our foremost men are aiming in their portraiture to produce the breadth of light and shade seen in the works of great painters, and while in many instances they succeed, yet in my opinion (and I give it for what it is worth) a large proportion of the so-called "Rembraudt portraits" are complete failures for want of gradation or middle tone. It behoves us, therefore, in seeking after higher and broader effects in our work, never to omit the half-tone, as otherwise heavy, lifeless portraits, with hard, staring faces, will be the outcome and conclusion of the whole matter.

Sir David Wilkie, the great painter (a study of whose engraved works is perhaps more fitted to elevate our efforts than those of any other artist, living or dead), was a master in the art of chiaroscuro, as witness his "Clubbists," in which we have a breadth and fulness of light and shade delightful to look upon.

The depth, brilliancy, and richness of this picture are not dependent on chalky high lights or black shadows, but upon the undulating gradations from dark to light, and from light to dark, which play so wonderfully over the figures and across the walls of the club-room. Detail and subtle gradation are found in every part, binding the masses of light and shade together, and giving to the picture a unity of purpose which it would not otherwise have.

The cultivation of this taste for combining the delicate with the deep, and high lights with half-tone, ought to be the aim of all photographers, as the forward movement of our art depends so much upon it; and just in proportion as the members of our profession exercise this faculty, by using the legitimate means at their disposal for giving gradation and modelling to their pictures, so will their work rise to a higher level, and claim a larger meed of praise from those men whose opinions are worth having.

No doubt we are "cribbed, cabined, and confined" in the production of art pictures by the unbending nature of the materials from which we make them; but then there is a hope that in the future—and, perhaps, at no great distance—some one will give us a developer so rapid in its action that those phases of expression we so long to get impressed upon our plates, and which, if once there, would give so much artistic value to our work, will become a possibility.

I would not forget that through the kindness of Mr. Faulkner the profession has now within its reach the invaluable power of giving breadth of effect and artistic gradation to the background of their pictures, and that without excessive labour; and although it is to be regretted that so few have as yet availed themselves of this great privilege, I cannot but believe that the profession generally will, ere long, come to look upon this method as a great help to securing beautiful pictures.

I may say here, with regard to my photograph "188," of which "the judges" expressed approval in their published report, that in my opinion the artistic merit, and what was termed "its perfect illusion," is, in a great measure, due to the use of one of Mr. Faulkner's graduated backgrounds.

When imitating the qualities of a fine engraving, we must not trust to toning-baths alone, but do what the engraver does—put the tone into our plates, not by aid of lead pencils, but with pencils of light direct from Sol himself; and assuredly, if an intelligent mind guides and controls these rays of light in the same way or sense as the engraver guides his graving-tools, all other things being equal, results will be obtained—in their technical qualities, at least—fit to be compared with the finest engraving extant. No remodelling of the negative, in the sense that many photographers mean it to be understood, if we are to judge by their work, can ever give that rich tone so peculiar to a well-lighted and carefully developed plate, even though the pencil be under the guidance of a Fritz Luckhardt.

A number of photographers who write in favour of retouching (or remodelling, as it is sometimes called) assume that artistic feeling and truthful representation must always be added to the picture after, and not before, the plate is taken!

Now I, for one, demur to this view of the case, and do not hesitate to say that this theory is damaging to the person who holds it, as well as to the profession of which he is a member. I do not think I am alone in believing that, unless artistic feeling and truthful representation be impressed upon the *subject* before the negative is taken, the

most elaborate retouching afterwards will not supply the want. I quite agree with Mr. Blanchard and others, that retouching is legitimate in the way of correcting any slight mistake when it occurs; but I am more and more convinced that the best negatives made are those which require the least work to make them ready for printing. And if this holds true in regard to particular plates, why should we not devote more time and greater skill to make all our negatives so perfect that little or no correction shall be needed to make them produce truthful and pleasing pictures? By doing so, character will be retained, the friends of the sitters will be better pleased (although the sitters themselves may not), and, not the least important, our art will be more respected and trusted in the future than it is likely to be if this frenzy for remodelling continues.

I would sooner have the photograph of a dear friend taken by the merest tyro in the art, than have one with all the character rubbed out, even though it should be pronounced a "pretty picture."

To secure this artistic softness in our plates, which is so much and so justly sought after, we must give them a very full exposure, so as to get out the minutest gradations both in the dark and light parts of the picture, leaving no more clean glass than is just needed to give depth and value to all the rest of the gradations above.

The negative must, through skill in lighting, timing the exposure, and developing the plate, be filled with tone, before we can get that delicious suggestion of flesh-tints in our portraits, and atmosphere in our landscapes, which pervades and fills to such a wonderful degree the works of eminent engravers.

I believe I am correct when I say that, however much we may differ regarding what should be the tint of our photographs when finished (a point on which difference of opinion may be held without materially affecting the intrinsic value of our work), most of us are at least agreed on this: that no tone or tint, however rich, will make up for a bad negative; further, that delicacy and technical perfection in the negative will not atone for the want of that knowledge and refined taste which grasps the idea and arranges the subject so as to make the best picture that can be secured out of the material we may have at our disposal.

(To be continued.)

## EFFECTS OF SUNLIGHT ON THE COLOURS OF PIGMENTS.

BY R. H. BOW, C.E., F.R.S.E.\*

WITH the three permanent colours—black, burnt sienna, and ultramarine—a most extensive and beautiful suite of transparent colours may be produced, ranging from the coolest neutral to the warmest ruddy brown, and with intermediate passages of grey, green, and blue character.

*Cappah Brown.*—So far as the sheet B can show, this colour is more permanent than vandyke. The exposure has not been long enough to speak of its absolute character as to permanency.

*Brown pink.*—Sheet A shows how decidedly fugitive this is. So far as sheet B goes it pronounces it more changeable than vandyke.

*Sepia.*—Sheet C shows this as decidedly bleached as vandyke brown.

*Bistre.*—On sheet C this is considerably bleached, and changed to a colder tone.

*Ferrocyanide of copper.*—On sheets B and C no decided change is observable.

*Brown,* formed by adding ammonia to pyrogallic acid.—The action of the light upon this is peculiar; it greatly increases the depth of the colour, at the same time changing it to a cooler character.

*Chromate of silver.*—This, which has an original colour like a darker and purpler Indian red, has, on sheet B, been changed to a warm brown. On sheet C the change has

gone very far, and even the obscured part has not been sufficiently protected; the exposed parts are bronzed and iridescent, like a much over-exposed ordinary photographic silver print.

*Chromate of mercury.*—This, which is originally like light red, has become on sheet B a dark, cool brown, and indeed, where the layer is thin, it is almost reduced to a neutral tint. In sheet C there is a change of colour without so great a darkening.

*Vermilion.*—This, as is well known, darkens in the sun. In sheet A it has assumed a dusky hue; in sheet B the change so far is rather one of tint than depth of colour, the changed colour partaking more of a brick-red character. In sheet C the change is as yet very slight.

*Rose madder.*—It is very satisfactory to find that this is particularly stable in oil colours, as shown by sheets A and B.

*Purple madder.*—This rather expensive colour, shown on sheet B, has faded very considerably. Whether or not some of the colours are genuine is, however, left in much doubt, as I understand it is too common a practice to adulterate the rarer ones. Judging from the rose madder, and from the character acquired by Turkey red, we should expect the madder colours to resist the sun.

*Crimson lake.*—This bleaches very rapidly.

*Carmine.*—Also very fugitive in the sun.

*Brazil wood.*—On sheet C a strip is painted with a red ink, believed to be made from this. It has become darker and more crimson in colour where exposed to the sun.

*Aniline colours.*—These are, unfortunately, very fugitive in the sun, as shown by Nos. 24, 28, and 34 on sheet C. Indeed, as a curiosity, a photographic print might be produced by exposing under a hard transparency a piece of paper stained with these colours.

*Indian yellow.*—This beautiful transparent colour, so useful in glazing, is, unfortunately, not permanent. On sheet A it soon lost its fine qualities, and finally became much weakened and reduced to a dirty greenish-yellow. In sheet B, though the change has begun, it is not yet very striking, and very little effect has been produced upon it used as a water colour on sheet C.

*Cadmium orange.*—This is very similar to Indian yellow. That purchased as a tube oil colour is considerably redder, but the pure sulphuret is somewhat yellower. No very perceptible change is yet produced on sheet B; but on sheet C the colour has become dirtied and impaired more than the Indian yellow on the same sheet.

*Aurcolin.*—So far as tested by sheet B, this appears to maintain its colour, which is very like that of the pure cadmium orange. There is a suspicion of darkening.

*Chromate of strontia.*—This, on sheet B, has lost somewhat of its brilliant lemon-yellow colour; on sheet C it has assumed a dirty-green hue.

*Chromate of baryta.*—This, on sheet B, has become more changed than the strontian yellow, but on sheet C the change is slight.

*Chrome yellow and orange* become darkened in the sun, and that, to a certain extent, very rapidly; but I suspect that they, like some other pigments, recover to some extent their proper colours when removed into the shade. On the extra sheet D are shown two strips—one of the pure yellow powder, the other the same fixed with British gum. An exposure for only five minutes in the sunshine caused a perceptible darkening, but most marked in the case of the mixture with gum; further exposure has not much increased the discolouration of the pure chrome, but the gummed strip has gone on darkening. In the old sheet A the change is very great. In sheet B the fine yellow colour is dirtied. In sheet C the change is not quite so striking, and on it the orange-coloured chrome is more darkened than in the yellow variety.

*Naples yellow,* on sheet B, is somewhat darkened.

*Gamboge,* on sheet C, is somewhat bleached.

*Oxide of uranium.*—This, though a good yellow at first,

\* Continued from page 184.

is here given merely as a curiosity, as it is so very greatly affected by the light, becoming, after no very lengthened exposure, a dark, greenish grey on sheet C, and nearly black in sheet B. Examined after exposure for three days, it was found to be very considerably darkened.

*Prussian green.*—This, as on sheet C, has lost in depth and become blue.

*Sap green* is not stable; the changes on the tincture will be afterwards spoken of. The strip on sheet C does not show much change, but the specimen was not very satisfactory.

*Oxide of nickel*, as an oil colour on sheet B, is unaffected as yet.

*Emerald green.*—On B and C no decided change as yet.

*Prussian blue.*—This, as an oil colour, appears to resist the action of the sun very perfectly, as shown by the much-exposed sheet A, and the later experiments on B, where it is given pure, and also mixed with white lead. This is a very satisfactory result; but, as a water colour, it is not to be trusted. Sheet C shows a bleaching effect at work.

*Antwerp blue.*—This, as a water colour, on sheet C, faded very soon.

*Indigo*, as an oil colour, faded less than expected. It became of a pinker character. It fades much more rapidly as a water colour.

The colours tried, but previously known to be permanent, were burnt and raw siennas, bright red, yellow ochre, terre vert, cobalt blue, and ultramarine.

The pigments which, used as oil colours, appear from the experiments to be characterised by more or less perfect indifference to sunlight are ferrocyanide of copper, Prussian blue, emerald green, rose madder, pure cadmium orange (?), aureolin (?), oxide of nickel.

In experiments with oil colours, it should be borne in mind that the yellowness of the medium becomes bleached in the exposed parts of the bands. This may cause an apparent change which is not due to the pigment mixed with it; thus, in the case of rose madder, the colour is rendered a more perfect pink in the exposed part from the whitening of the medium. The medium recovers slowly its yellowness in the shade.

I have now to speak of that brilliant but most treacherous of all colours—the biniodide of mercury, or “pure scarlet” of the shops. The experiments with it will serve to show what great influence the medium used has upon its permanency.

When the biniodide is formed by precipitation—as by pouring a solution of iodide into one of corrosive sublimate—a lemon-yellow cloud is formed, which rapidly changes colour, running through orange, salmon colour, &c., and more slowly changing to the brilliant scarlet. When this is used as a paint under a considerable variety of conditions, there is a great tendency for it to revert to the yellow condition, and that preparatory to its complete disappearance. Since it is by far the most perfect of scarlet pigments, it is most important that its characteristics as to permanency should be studied. It has happened that naturalists have been induced to use it to depict, among other subjects, the beautiful colouring of tropical flowers; but, alas! when the painting was to be referred to in after years, the colour had either altogether disappeared, or degenerated into scattered yellow and red spots and streaks. I believe, however, that I have been fortunate enough to stumble upon a treatment which will confer upon it a certain degree of permanence.

The biniodide is liable to two changes—the one becoming yellow, the other darkening in the sun. And, first, concerning the tendency to darken. When the simple powder is exposed for a few seconds to the sun, or even diffused daylight, a very perceptible darkening is produced, and when British gum is used as the medium, this change is still more decided, as seen on sheet D\*; but when *gum arabic* is used so

abundantly as to give a high gloss to the surface, no decided change is produced, even after lengthy exposure, as shown by sheet C. Oil mediums and varnishes do not prevent this darkening. On sheet A it assumed the colour of Indian red, a dark powder appearing to be thrown out, which a wetted cloth readily removed, showing the biniodide beneath it even paler than originally; but the spot so cleaned became even darker than before on re-exposure. This darkening, however, begins to disappear when the sheet is removed to the shade. It may be that the darkened particles tend to become yellow. In sheet B the behaviour is more capricious; the exposed parts are sometimes darker and sometimes lighter than the obscured part. This, I believe, arises from both changes to darkness and to yellowness going on at the same time, but in irregular degrees. I must, however, at present leave the matter in a very obscure state.

The supplementary sheet E, painted some years ago, will show the tendency to turn yellow or disappear altogether. The first strip, painted with the pure powder in water, has nearly all vanished, a few yellow streaks and some minute red spots only being left. The second strip had flour paste as the medium, and its condition is very little, if at all, better. The fourth strip was painted with the biniodide mixed with varnish: a yellow and red cloudiness is all that we now see. The fifth strip had magfly for the medium: this is reduced to a faint yellow with some red streaks through it. But the third strip, for which the medium was a thick solution of gum arabic, retains very much of its original body and brilliancy. The sixth strip was painted at a later date, and gives a different result from the fifth for magfly as the medium; it as yet shows no loss of body.

Gum arabic appears, then, when liberally used, to have the power of preventing both the darkening by the sunshine and the yellowing from molecular changes.

I shall conclude by exhibiting two instances of change of colour in liquids caused by the sunlight. Here are two bottles containing tincture of green leaves, the colouring matter being chlorophyll, which has such interesting optical properties. The two bottles were filled from the same stock, but one of them has lain for about two hours in the sunshine, and you see the colour has been degraded from the beautiful and somewhat blue green to a sort of brown yellow, having only the faintest trace of green in it. The other example is an old registering minimum spirit thermometer. This was used for some years as a garden thermometer, and you may observe the liquid, which originally possessed a fine pink colour, has become bleached to a faint dirty yellow, and very unsuited for its purpose. I also place on the table a small spirit level which I filled a number of years ago; but the coloured liquid in it is as clear as when put in, and the colour is perfectly permanent. I would strongly recommend the adoption of this liquid, which is a tincture of iodine, for spirit thermometers and other similar purposes.

## SPECTRUM ANALYSIS AND PHOTOGRAPHY.

BY J. NORMAN LOCKYER, F.R.S.\*

THE next step brings us down to the year 1852. In this year a paper was communicated to the Royal Society by Professor Stokes, who had already announced his discovery of what has since been called fluorescence, “or the long spectrum of the electric light.” Professor Stokes dealt in his first paper with the “change of refrangibility,” or, as Sir William Thomson proposed to call it, “degradation of light,” by virtue of which light, which was generally invisible to us, could, under certain circumstances, be made visible. It is no part of my present purpose to go into this magnificent paper, one of the crowning glories of the work of this century, at any great length; but you will see in a moment that if it was a question of the degradation of light, then the invisible light to which Professor Stokes referred as being capable of being rendered visible must have been light outside the blue

\* After a few days the changing to yellow becomes so decided as to do away with the darkening by the sunshine; but this yellowing is not decidedly shown in the shaded part of the strips of colour.

\* Continued from page 185.

† *Philosophical Transactions*, vol. clix., 1852.

end of the spectrum, and not outside the red end. Professor Stokes, in his investigations, in order to get at this invisible light under better conditions if possible than those with which he commenced operations, tested the transparency of the substance through which the light with which he experimented passed, and the transparency of glass was passed under review by him,\* when he found that this invisible light, or whatever it was, could only get through glass with extreme difficulty. Continuing his investigations, he found that quartz, on the other hand, allowed this invisible light to pass. If you will allow me, I will read an extract from Professor Stokes's paper of the extremest importance to our subject. After referring to these experiments on glass and quartz, he proceeds to say:†—"I have little doubt that the solar spectrum" (which you recollect had already been photographed to a certain extent both by Becquerel and Draper beyond the visible blue end of the spectrum), would be prolonged, though to what extent I am unable to say, by using a complete optical train, in every member of which glass was replaced by quartz." He then adds that other substances which suggested themselves to him were not equally good; then, further, that if this invisible light does get through quartz, and does become visible to the eye, it does not at all follow that it will be capable of being photographed, because already Professor Stokes, in order to continue his researches in fluorescence, had been, as it were, driven to photograph some of the results which he had thus obtained. I am sorry to say that, so far as I can find out, none of those photographs have ever been published.

Before I go further, I think it will be convenient to throw on the screen some photographs of the solar spectrum, showing exactly what I mean by the "invisible rays;" and you will then see the enormous advance which Professor Stokes made the moment he introduced his quartz train, and enabled both the eye and the photographer to take advantage of a new region of the spectrum in its entirety, in order to investigate it. In a note to his paper communicated to the Royal Society, he shows that his anticipation, so far as the eye was concerned, was perfectly justified by the facts.‡ He says:—"I have since ordered a complete train of quartz, of which a considerable portion, comprising, among other things, two very fine prisms, has been already executed for me by Mr. Daker; with these I have seen the lines of the solar spectrum to a distance beyond II," more than double that of P, so that the length of the spectrum, reckoned from II (the outside line in the portion ordinarily visible), was more than double the length of the part previously known from photographic impressions. I will now throw on the screen the spectrum of the extreme part of the visible portion. The eye generally can see the two dark bands which you see in the middle of the screen, called H 1 and H 2. The less refrangible part of the spectrum lies to the right. When Professor Stokes, therefore, stated that the solar spectrum was prolonged, he means that the part of the spectrum visible either to the unassisted eye or on a photographic plate after impression, extends to a certain distance beyond these two dark lines. Another photograph I have here will show this better. In this we get a little more of the structure of the spectrum beyond II. We have still the less refrangible portion to the right. This is a negative, and therefore what we have as dark lines in the proper representation of the solar spectrum are seen as bright lines; we have to the left of H 1 and H 2 more of the structure than we had before; just about so much of the spectrum, in fact, as was photographed by Draper and Becquerel in 1812. The part which Professor Stokes rendered visible by means of his quartz train extended a considerable distance to the left beyond the part of the spectrum which you now see on the screen.

So much for the solar spectrum. Now let me carry you on another ten years, to the year 1862. Professor Stokes, in a paper communicated to the Royal Society in this year,§ refers to his former paper, and to what he had been enabled to do by means of it. He states: "A map of the new lines (the lines thus observed by him) was exhibited at an evening lecture before the British Association, at their meeting at Belfast in the autumn of the same year, and I then stated that I conceived we had obtained evidence that the limit of the solar spectrum in the more refrangible direction had been reached. In fact, the very same arrangement which revealed, by means of fluorescence, the existence of what were evidently rays of higher refrangibility coming from the electric spark, failed to show anything of the kind when applied to the solar spectrum;" and then he goes on to say that, in making

observations by means of the electric spark, he had found that in the case of a spark taken between the poles of an induction coil like this on the table, or between the poles of an electric lamp such as you see here, that the visible spectrum which was revealed and rendered visible to him by means of fluorescence was no less than six or eight times longer than the whole of the visible part of the spectrum. That, you see, was a revelation of the first order. He was so astonished at this, that he at first thought there was some mistake: "I could not help at first suspecting that it was a mistake, arising from the reflection of stray light." In fact, so astonished was he, so many methods did he try in order to break down the impossibility, if it existed, that he adds, in a subsequent part of the paper, "I tried different methods, without being able to satisfy myself as to the accuracy of the observations, and frequently thought of resorting to photography."

Professor Stokes thought of resorting to photography, but at the moment that Professor Stokes was thinking of this, Dr. Miller, of King's College (unknown to Professor Stokes), was not only thinking of resorting to photography, but had actually resorted to it, and was taking photographs of the so-called invisible part of the spectrum, in which the spectrum in the case of some substances was five or six times, and in the case of silver one might say almost seven times, as long as the spectrum ordinarily visible through glass prisms. Professor Miller goes very nearly over the same ground that Professor Stokes had done before him. He also investigates the transparency of quartz, and comes to the conclusion that quartz is almost the only substance that can be employed. Professor Miller, in this paper, which you will find in the "Philosophical Transactions,"\* also gives for the first time a detailed account of the way in which such work is done. Permit me to give you a rough notion of this method of work. We have here a spark from an inductive coil, exactly such a spark as Dr. Miller wished to examine. He had a spectroscopie something like this on the table, with two important differences. The first important difference was, that instead of having two glass prisms, he had prisms of quartz; and again, instead of having an observing telescope adapted for use by the eye, he inserted a camera, or what was to all intents and purposes a camera, in the same place. So that he had, first of all, a light source by which you get an intense illumination, due to the extremely high temperature of the spark. Then you have a quartz lens and quartz prisms, and then simply the photographic plate. Having, therefore, an entire absence of the non-transparency of glass, Professor Miller was delighted to find that, on taking this spark in this way, between electrodes of different substances, he not only photographed what could be seen—namely, a spectrum ranging from red to blue—but one extending, as a rule, six times the length of the visible spectrum beyond the blue; although, in some cases, it is true, it is only four times as long on the more refrangible side of II as II is from the red end of the spectrum—that is to say, the line which is generally called A. In this paper of Dr. Miller's we have the germ of all the applications of photography to spectroscopic inquiry which have been carried on since; and I am sorry to say that altogether too little has been carried on. Not only did Dr. Miller investigate in this way the radiation of different vapours, and give photographs for the first time of the bright lines of a very large number of chemical substances, but he went further than this altogether, and dealt with the absorption of different substances. He commences his paper with the absorption of chemical rays by transmission through different media—through solids (transparent, of course), through liquids, and through gases and vapours, the only alteration he made in his general mode of experimentation being that in the case of the absorption of gases and vapours, he placed the instrument further from the light source, and in the path of the ray inserted a tube containing the gas or vapour to be experimented with, as I am doing now, so that the light which passed from the spark to the telescope was compelled to traverse a thickness of vapour according to the length of the tube employed. In that way he not only determined the absorption of equal lengths of different vapours amongst themselves, but the absorption of different lengths of the same vapours; his paper is thus one of the most important contributions to spectroscopic knowledge that I am acquainted with, and I hold that the chief importance of it is the application of photography to spectroscopic observation. There is nothing so difficult, I think, as to make a proper spectroscopic observation, and from the little experience I have had with it at present, I should think there is nothing more easy than to make what I may call passable spectroscopic photographs. That, then, was in the year 1862.

## COMPETITION FOR LANDSCAPES.—FURTHER PRIZES BY MR. CRAWSHAY.

WE have pleasure in announcing that Mr. Crawshay, of Cyfarthfa Castle, to whose munificence photography has already been indebted for considerable impulse in the production of large direct portraits, has resolved to add to the prizes already offered for large portraiture, a series of prizes for landscape pictures, the competition to take place some time in autumn at the same time as the portrait competition. A prize of £25 will be offered for the best three landscapes of any size not less than ten inches by eight, and a second prize of £12 for the second best three of similar proportions; also a prize of £10 for the best landscape of any size, and a prize of £5 for the second best landscape of any size. The precise arrangements will be duly published in our next; but at present we may remark that no conditions of a troublesomely restrictive character will obtain. Mr. Crawshay is desirous that each landscape shall be a genuine view of the scene it professes to represent, and not a patchwork of many places. But he does not bar such combination as may be desirable to secure either higher truth or pictorial effect. If the subject be one in which justice cannot be secured by the use of one negative, several negatives may be employed, so that portions of foreground, figures, clouds, &c., may be produced on separate negatives, and secured in the picture by combination printing. The competition will be open to photographers in all parts of the world; and as the wide conditions give facilities for almost every landscape photographer to compete, we hope that a goodly number will enter the lists. The size of the competing pictures for the first prize is within the power of most photographers, whilst for the next no size is laid down. Supreme excellence alone will take the prize. Fuller details will appear in our next, and the precise time and place of the competition will be duly announced when decided.

## AWARD OF MR. E. ANTHONY'S PRIZES.

IN the course of last year, our readers may remember, Mr. E. Anthony, of New York, offered a series of five prizes, of one hundred dollars each, for the best whole plate photo in five different styles. There was a certain charm in the simplicity of the demands which was likely to draw many competitors. None of the subjects for competition demanded extraordinary appliances or the expenditure of effort of a kind out of the groove of ordinary business. The first prize was for a bust of a lady; the next the head of a boy under six; the third the head of a girl under six; the next a group of two children under six; and the last the best

landscape,—none of the pictures, as we have said, exceeding whole plate size. All the subjects were, therefore, within the scope and means of every photographer, and the competing pictures might, in many cases, be selected from those taken in the course of business. Over a hundred competing pictures from all parts of the world were sent in—England, New Zealand, Bavaria, and other places, as well as the United States, furnishing competitors. Curiously enough, in the large competition evoked, many contributions were necessarily excluded for contravening the conditions, by being larger than the prescribed size. Three jurors, Messrs. J. W. Draper, H. J. Newton, and F. F. Thompson, met in New York, and reported as follows:—

"1. For the best bust picture of a lady, to J. Barhydt, of Rochester; the photograph marked lady, No. 3.

"2. For the best child's head (boy), less than six years old, to F. Gutekunst, Philadelphia, the photograph marked little boy, No. 1.

"3. For the best child's head (girl), less than six years old, to F. Gutekunst, Philadelphia, the photograph marked little girl, No. 1.

"4. For the best group of two children under six. The pictures presented under this head were all indifferent, and the jurors do not award any prize, unless the terms of the competition require them to do so. In that case they give the preference to the photograph marked Nellie and Eddie, by L. J. Bigelow, with John F. Nee, Williamsport, Pa.

"5. For the best landscape, to Alexander Henderson, of Montreal, his motto being 'Lux fecit,' and the photograph marked 'the A. House.'

"The Jurors further state, that with regret they were constrained to exclude from the competition, because of their size being very much larger than the prescribed 4-4, the very fine landscapes sent by B. Johannes, Partenkirchen, Bavaria. These are excellent both for tone and effect, and are worthy of the highest commendation.

"Several portraits of gentlemen were also excluded, there being on the prize-offer no provision for them."

Mr. E. Borda and Mr. Coleman Sellers met in Philadelphia, and, in sending in an independent report, agree with the preceding report as to the bust of the lady and the two portraits of children; but awarded the group to M. Boissonnas, of Geneva, Switzerland. In regard to the landscape, they agree with the New York jurors.

Mr. J. P. Cook, of Harvard College, in an independent report, agreed with the preceding as to the portrait of a lady; but gave his verdict in relation to the portraits of a boy and a girl to contribution by Mr. Abel Lewis, of Douglas, Isle of Man. He also gave his verdict for M. Boissonnas in regard to the group, and for landscapes to Johannes, of Bavaria.

A final decision in favour of M. Boissonnas was given by a painter and member of the Academy of Design, Mr. G. A. Baker, to whose decision the matter was referred on the subject in the absence of agreement amongst the jurors.

## THE PHOTOGRAPHIC SOCIETY OF LONDON.

THE Photographic Society of London appears to be once more in a state of disruption and confusion, and—although, so far as we can see, with less cause—we fear that the prospect of harmony is more irretrievably remote than ever. We can readily understand how puzzling to non-resident members must be the glimpse of the matter they obtain from published reports. Being personally unable to be present at the last meeting, and reading the reports at a distance far removed from the atmosphere of strife, we can feel, to some extent, the difficulty which must be experienced by the mass of the members of the society in appreciating or entering into the spirit of the struggle by which a small section, chiefly amongst the resident members, has perilled the prosperity, possibly the existence, of the whole society. In our absence, we engaged a shorthand writer, connected with the London press, to furnish us with a full report, free from bias or tincture of partizanship. This report we publish this

week, to supplement the brief notice in our last. We feel it impossible to glean from the detailed account any legitimate or adequate reason for the renewed disruption; but there unquestionably seems to have been an unnecessarily exigent spirit on both sides, Montagnes and Capulets. "Do you bite your thumb at us, sir?" on the one hand; and "I bite my thumb, sir," on the other.

Let us glance for a moment at the facts. After a brief, but bitter, agitation, the origin and character of which it is neither necessary nor pleasant to recall, a meeting was held last month at which an honest spirit of conciliation and harmony prevailed, and a resolution was passed inviting the president and members of council, who had resigned at a former meeting, to resume their offices. These gentlemen, having met, agreed to accept the invitation, for such brief time as might be necessary to conduct the business of the society until a new code of rules was in force, an event which it was hoped would not require more than two or three months, at most. They would then resign their offices, in order that a general election might take place under the suffrages of every member of the society, non-resident as well as resident; recognition of the voting rights of country members being the corner-stone of any new laws which the council were willing to promote or sanction.

A series of doubts and difficulties arose, however, in the minds of different members of the council, as to the legality, on various grounds, of the proceedings following the resignation of the council. It was held by some that an annual meeting for the transaction of business was dissolved when the president left the chair. The rules provide that in the absence of the president, one of the vice-presidents or one of the council shall preside. In this case, all officers having resigned, a non-official member present in the meeting took the chair; and, as we have said, it was held by some that the business meeting was *ipso facto* closed when the president left the chair, and all business proceedings, including the election of six officers, afterwards transacted at such meeting, illegal. It was further held by others that the entire spirit of the vote by ballot was violated by the election of six officers by a score and a-half of members pledged openly to vote for them, and doing so at a meeting when all, or nearly all, opposed to them in view had retired. It is probable that some idea of the illegality or unfitness in some form of the manner of their election was felt by these gentlemen and their friends, as they resigned office at the next meeting. It will naturally be answered that having done this, and been re-elected, any illegality in their election at the former meeting was disposed of. But another difficulty arose. The election of officers must, according to the rules, be by ballot, and in the re-election of these six gentlemen no ballot was taken, but a simple show of hands. Again, it may be urged that it was in precisely the same manner that the late council were invited back to their offices. But there is just this important difference: that in their case there was no re-election, and therefore no breach of rule. They were invited to "resume" office, and this they expressed their willingness to do by withdrawing their resignations, not by being re-elected.

These and some other similar arguments may be valid, or they may not, and it is unimportant now to discuss them, as a decision either way cannot undo what has been done. We simply state them to explain the course of events. In the midst of the difficulties, and with a strong indisposition to return to office at all, the council yielded to a desire to serve the society, by consenting to resume temporarily their duties, without the co-operation of the gentlemen whose legal status was doubtful. Whether they would continue those duties alone, or by the aid of other members elected in accordance with an existing bye-law, was undetermined. But we may remark that we have reason to believe that a majority of the council were prepared, at the first business meeting of their body, to have voted for

election into that body the six gentlemen who were re-elected by show of hands at the March meeting; and we have, further, the strongest assurance that had matters not been brought to an untimely issue on the evening of the fourteenth, the six gentlemen who have been acting as a committee to revise the laws would have been again elected, in conjunction with some three others, to proceed with the revision of laws. We mention these circumstances simply to illustrate the fact that a spirit of conciliation was intended by the council, and that, in assuming that the invitation to resume office involved a resumption of the *status quo ante*, they felt that the only safely legal and honourable course was adopted; but they were prepared to place matters upon a legal footing in a conciliatory rather than an antagonistic or belligerent spirit.

Many of our readers will exclaim: But if this were so— if conciliatory overtures were made on the one hand, and accepted in a conciliatory spirit on the other—how, in the name of all that is reasonable, did the first meeting afterwards issue in fresh and irreparable rupture? This is just the question to which we can find no adequate or satisfactory reply. The report which we publish on another page furnishes none, and we can glean none from various communications we have had on the subject. It must be confessed that the remarks of the President at the outset of the meeting, to the effect that he felt he was making a mistake in resuming office, were not reassuring, and his remark that he should not so resume on the decision of a mere majority seemed almost in the character of a challenge, which a dispassionate looker-on might call injudicious. By a unanimous vote he and his colleagues were, however, again invited to resume office, and absolute peace seemed to have been secured. But a cloud was on the horizon. A spirit of distrust or antagonism still existed somewhere, and Mr. Hughes—we presume as the mouth-piece of the former opposition combination, which, we are informed, had been again invoked to combined action—challenged the position which the president and council had assumed in returning to office as not in accordance with the vote of the preceding meeting. So far as we can glean from the report, this was done moderately enough, but scarcely accurately. Assuring Mr. Glaisher that he was not correctly informed of the nature of the proceedings at the March meeting, Mr. Hughes proceeded to state them incorrectly. He stated that the meeting *elected* the president and his colleagues. This is an error. The terms of the resolution simply invited a *resumption* of office, and that resolution only did, and only could, refer to those colleagues who resigned with the president. The position of the other six gentlemen was based, as we have indicated, upon entirely different conditions. We think Mr. Hughes, or his party, was unwise in raising this issue at that time, and we cannot but think that the president was unnecessarily hasty in declining to enter into explanations, and at once assuming that the expressed doubt of an individual, or a party, was a sufficient reason for declining the unanimous invitation of a large meeting. As to the statement made in the report that Mr. Glaisher's only alleged ground for declining to act with the six gentlemen in question was that not one of them was a nominee of the council, we cannot but think there must have been some mistake, that he must have been misunderstood. As the law distinctly provides for society lists as well as council lists of nominees for office and officers elected, when such opposition lists exist are more truly and honourably elected by the society than any can be when no such occasion exists to bring the ballot into exercise, it seems simply incredible that the president should allege such a ground of objection; the more so when it is remembered that he has on former occasions expressed a conviction that the sturdy exercise of their rights and privileges by members was a sign of health in the society. Some mistake, no doubt, exists here.

Probably, as we have already suggested, too much of

the spirit of Montague and Capulet existed, and the crossing of swords was inevitable. All the same, it is a serious, if not a fatal, misfortune for the society. Whatever may be the varied views of individuals—and the case has assumed aspects which render varied views almost inevitable—there cannot be a moment's doubt as to the resignation of the council generally. Very few of them were present at the meeting in question; but all from whom we hear express their unhesitating and unchangeable resolve to retire. The charge of *camaraderie* has been somewhat amusingly brought against the council by some of the opposition—amusingly, because by the use of a French word to express the idea, it seems to be supposed that fellowship is a crime—but one thing is, we fear, for the prospect of peace we fear it, certain, namely, that sufficient *esprit des corps*—to borrow more appropriately from the French—prevails amongst them to ensure unanimity in this matter, the end of which is, after all, but the legitimate issue of the ill-judged agitation with which it commenced.

#### REPRODUCTION OF NEGATIVES.

M. GRAND, in the *Bulletin* of the French Society, describes, as a novelty, the method we suggested nearly two years ago. He says:—

"The necessity of reversing the negative when printing in carbon, or to work by double transfer if the former is employed in its ordinary state, has been one of the drawbacks to the practice of printing in pigments. To obviate the difficulty, it has been proposed to make a counter-cliché, and MM. Geymet and Alker have published a powder process, which, I fear, differs too much from ordinary processes to give good results in the hands of photographers other than the authors.

"The following is a means, already well-known, to obtain direct, one negative from another. It is only requisite for the operator to be conversant with alkaline development. You put under the negative a prepared dry plate, one of collodio-bromide, expose rapidly in the printing-frame, and develop with pyrogallie acid and ammonia, until you have secured a good positive transparency. This positive is then dipped into nitric acid, diluted with its volume of water. All the silver will be in this way dissolved, and there will remain upon the plate a very transparent negative image, formed by the bromide of silver not reduced.

"This image is now exposed to light until it has acquired sufficient density, when it is fixed with hyposulphite. A counter cliché will then have been produced in which none of the half-tones are lost. Moreover, by this method, negatives which are too opaque to give good results in carbon printing may be reproduced in a modified and improved form.

"I believe that this method is more simple than that proposed by MM. Geymet and Alker, and gives a better result than the Poitevin process, which requires the aid of camera and lens."

#### JOINING THE PHOTOGRAPHERS' BENEVOLENT SOCIETY.\*

SCENE OUTSIDE A STUDIO.—CLOSING TIME.

"HAVE you seen this, Mr. Headrest, the Rules of the Benevolent Society?"

"Yes, I read them over, and thought, if one or two others would, I would join."

"Pooh! It will never come to anything! What do you or I want with such an affair? True, I was out of a 'sit,' a long time last winter, but somehow, like the cats, I always come on my feet."

"Yet I have heard you say you were awful hard up, and could have had a 'sit,' down North, but had no money to take you."

"Well, yes; and I had lent all I had to give to my mule, you know—the chap on the corner with the three golden balls over the door."

"Just so. Now, don't you think it might happen again, and it would be very nice to be able to ask for a little help as a right to go to a 'sit,' or, if you were ill, what would you do?"

"Oh, as to illness, I am in a club; so are you, are you not?"

"Yes; but the club will help you only when ill, and the help then doesn't last long. What should I do if I were out of work a long time, and ill, and all my money gone? It would be nice to know I might have a place, but could not go to it for want of funds—very nice; and I having a wife and two children to keep!"

"Ah, there you are! I have no wife. But if you want to preach providence, come and have a glass of beer; it's dry talking. What do you say—you never drink until after the evening meal? Well, I do, sometimes two or three; but you have your wife to think of, and never drink much at all, I suppose?"

"No. What does a man want with much, as you call it? A glass or so in the evening is very well. And look here; the subscription is three shillings per quarter, if you like to pay that way—not the price, or barely the price, of a pint of beer a week. Don't you think you could drop the pint of beer and join?"

"I see you are on, my friend. You had better become local secretary for these parts—they want some one—and then you will see how many are going in. Get all the operators, retouchers, and ladies to join. What does a poor d—l of a printer like me want with it? When you have twenty members, I will join."

"As to being local secretary—well, I will think of it. In the meantime, you drink a pint of beer less a week, and send the money to Mr. Wilkinson; you won't regret it some day. Good night!"

"Good night!"

#### Correspondence.

##### MAGIC LANTERN IMPEDIMENTA.

SIR,—I have read correspondence respecting gas bags for dissolving views, and believe, with Dr. J. Nicol, that the plan of bag (square or camera shape) is labour in vain, and useless; and, could it be used, would be more trouble than the old wedge shape. I have found great difficulty in borrowing weights when out exhibiting, except the old round weights, and I have been in constant fear during the exhibition lest they should roll off.

I have used the square weights, also flat bars (which are decidedly the best), and I would say to all readers who use bags, do not be led away by all sorts of suggestions, but use those you know will answer and be safe, without constant fear of accident.

I know the gas bags, pressure-boards, and weights, are very cumbersome articles for travelling. I have abandoned them for two seasons, and am now constantly using the compressed oxygen and hydrogen gas in iron bottles, and find them very convenient for travelling and also home use. For the aid of many who may not know of them, I will describe them. A wrought-iron bottle, about three-sixteenths of an inch thick and four inches diameter, twenty-seven inches and thirty-six inches long, according to number of foot of gas required. Twenty-seven inch will hold seven feet; thirty-six inch, ten feet. At one end is a brass connection, which contains a valve of steel worked by a moveable handle to take off and on, and a union is fixed to connection to fix india-rubber tubing to jets. I also use a gauge, which tells me exact quantity of gas remaining, or being used in a certain given time.

The gas is pumped in to four hundred and fifty pounds pressure to the square inch, and, if seven feet of gas be used, it will last two sets of jets, by the aid of dissolving tap, about three hours. The cost of bottles filled with gas is about forty-two shillings and sixty-three shillings each, and they can be refilled at the usual prices. The bottle weighs about fourteen

\* From a Correspondent.

ponnds and is very portable, and perfectly safe in careful hands. Great care must be used in opening valvo, as a very slight movement of the handle will give an increase of supply. The handle can be taken off, so that an inexperienced hand could not possibly let the gas out.

Should any of your readers require further information upon this subject, I shall, with your permission, be most happy to give it.—Yours, &c.,  
W. H. OAKLEY.

#### ELIMINATING HYPOSULPHITE OF SODA FROM PRINTS.

SIR,—Permit a simple amateur photographer, a constant reader of your excellent journal, to submit some observations on the subject of eliminating hyposulphite of soda from positive proofs on paper.

I have but little confidence, I must confess, in the employment of chemical solutions for the purpose of converting the hyposulphite of soda into any other compound, respecting which there is uncertainty as to its entire removal from the paper, and consequent ignorance of its ultimate influence upon the prints.

I am surprised that, in the endeavour to solve this difficult problem of the preservation of the positive proofs, so little attention is given to the remarkable process which you, sir, have invented, and which bears the name of collodio-chloride paper.

This paper, as it appears to me, possesses the following advantages:—Undoubted superiority over all albumenized paper, on account of the rapidity in printing, extreme and brilliant finish of the image, preservation for months of its sensitiveness, perfectly white, without special preparation, the ease with which it can be effaced, and, above all, the ability of fixing by means of a very weak solution of hyposulphite, which one may be sure of being able to remove by means of careful washing, the analogy being complete with the negative process, because the chloride of silver is contained in the pellicle of collodion, and not in the tissue of the paper.

For an amateur, unfortunately, the preparation of the collodio-chloride paper is difficult. That which is to be found in the trade, manufactured by Obernetter, of Munich, is good, but very dear. The point, however, to which I should desire to draw your attention would be, sir, that you should use your influence, on the one hand, with the manufacturers of photographic paper to devote themselves to the manufacture of collodio-chloride paper, so as to be able to sell it at a cheaper price than at present, which ought to be possible; and that, on the other hand, you should advise photographers to use this paper, of which the only inconvenience is a disagreeable tendency, sometimes, to curl, for which defect the manufacturers may, however, find a remedy, either in modifying the nature of the paper, or in choosing some other support for the pellicle of collodio-chloride.

Please excuse the length of this letter, and believe me, &c.,

PIERRE REVON, Banker.

Member of the Council of the Arrondissement of the Canton of Gray.

Gray, 14th April.

### Proceedings of Societies.

#### PHOTOGRAPHIC SOCIETY OF LONDON.

A MEETING of the above society was held on Tuesday, the 14th, at the Architectural Gallery, 9, Conduit Street. Previous to taking the chair, Mr. Glaisher, addressing the meeting, said that when he left that room a little time since, it was with the firm resolve never to return to a position to which he had never aspired. He had found the duties very exacting, taking a great deal of his time—and his time was valuable. When circumstances arose causing him to leave, he had determined not to return. It had, however, been represented to him by many gentlemen whose opinion he valued, that it would be for the good of the society if he were to return, if only for a short time. It had also been told to him it was the unanimous wish of the society that the council should return to take upon themselves a continuation of those duties to which they had been so long trained, and they with himself had agreed to accept for a time. The position he (Mr. Glaisher) occupied was an anomalous one, and one in which he felt he was wanting in power. Indeed, he scarcely knew his own position, nor did the council know theirs, but they had returned because they wished to do the

society good. It was with this feeling they wished to act. He (Mr. Glaisher) desired, however, to say that before he took the chair he would wish to know whether it was the unanimous feeling of the meeting that he should return. If there were a difference of opinion among them, if the minority be of the smallest, he should feel inclined to leave that room. At the same time, if it were their wish he should still be their president, he could but feel, in accepting, that he had made a mistake. If any gentleman had come to him and had represented the tone and manner in which he had been driven away, he should have said, "Do not go back." Therefore in returning he felt he was making a mistake. He did not like to do things by halves, and what he did he wished to do well and earnestly, but he knew that many instances of earnestness would be brought forward as instances of his over-bearing character. However, if it were their unanimous wish he should return, he was willing to do so, and he believed the council would do the same.

The question was then put to the vote, when every hand was held up in the affirmative.

Mr. GLAISHER then expressed his desire, and that of his colleagues, to use their best exertions for the good of the society.

Mr. SOPWITH, having congratulated the president upon his decision, which he felt sure would prove beneficial to the society,

Mr. Jabez HUGHES observed that occupying, as he did, the position of chairman at the previous meeting, he gathered from the statements just made that Mr. Glaisher had been scarcely accurately informed of what took place on that occasion. It was true that the meeting did then elect the president and his colleagues, and were very pleased to have the opportunity of so doing. Upon the present occasion, when the question was asked, they most distinctly said yes; at the same time there was a little complication which it was most desirable should be cleared up. What he (Mr. Hughes) wished to know was, who were the colleagues of the president, inasmuch as a certain number of gentlemen were elected on the same occasion when the president and council were re-elected? If Mr. Glaisher meant that the six gentlemen elected at the February meeting were considered to belong to the council, he (Mr. Hughes) was sure the affairs of the society would work in that harmony which all would be too happy to see.

Mr. GLAISHER, in reply, said that after Mr. Hughes's remarks he was glad he had not taken the chair. It was a condition laid down, in the event of himself and his colleagues returning to office, that he should not work with those six gentlemen—not on any personal grounds, for he should be glad to act with any one of them, but because not one of those gentlemen was a nominee of the council. If the conditions laid down by himself and his colleagues were not accepted, there was but one action for them to take. Those conditions were well understood, and if Mr. Hughes said they were not accepted, there was but one way out of the difficulty.

Mr. HUGHES said he was but expressing his own sentiments, and not those of the society. As it was distinctly stated that the president and council would not return unless the six gentlemen were excluded, would Mr. Glaisher kindly tell the meeting the reason why? They had often been told that they always elected the nominees of the council, and had been asked why, if they disliked doing so, they did not nominate others? Once only, at the last February meeting, had this course been adopted, and of the six elected, three had been former members of the council, and one a former nominee.

Mr. GLAISHER repeated that there was not one gentleman of the six with whom he would not be glad to co-operate. It was the manner in which the business had been conducted that he objected to. As, however, there were dissentients, he must decline to resume the chair. He could not consent to occupy it unless there was a distinct understanding that he should work in perfect freedom.

Mr. HUGHES again put his question whether the re-election of the president and council meant the ignoring of the six? In reply to which,

Mr. GLAISHER said he must decline to enter any longer into the question, as he should absolutely decline to act with the six gentlemen. That being the case, there was but one thing for him to do. As for his colleagues, he must leave them to act individually as they pleased.

Mr. GLAISHER then quitted the room, followed by Lord Lindsay, Mr. H. White, and Mr. Mayland.

Col. STUART WORTLEY then proposed that the senior vice-president take the chair.

Mr. S. FRY seconded, and after some remarks from Mr. S. Davis and Mr. Hughes, Mr. Spiller consented to act as chairman.

Mr. SPILLER observed that he was called to occupy the chair at an exceedingly awkward and difficult moment; but in doing so he must earnestly beg of all to have the true interests of the society at heart, and endeavour to find some way in which to conciliate the president and the retiring members. The next few minutes would decide the future history of the society. Mr. Glaisher had worked well and earnestly during many years, and the society owed him a deep debt of gratitude. He (Mr. Spiller) would ask whether a vote should not be taken to invite him back, as he feared he would for ever be lost to the interests of the society. Having witnessed for so long a time Mr. Glaisher's great achievements, he (Mr. Spiller) earnestly wished to see him resume his position in the society, and if the meeting would waive for the moment the legality of the election of certain six members of the council, the dilemma would, perhaps, be got over, although, for himself, he could give no guarantee that the president would be induced to return.

Mr. BIRD was sure that, though there seemed to be a good deal of thunder in the air, all that was really desired was a reform in the constitution of the society. There was no ill-will whatever against the council, and at the very first meeting it was generally felt that the position of Mr. Glaisher should not enter at all into the question. He could not see why so much temper should have been introduced into the discussion. As for any little asperity on the part of the requisitionists, that had been fairly atoned at the last meeting, when the greatest regret was expressed for what had been hastily said. However, as Mr. Glaisher had expressed his determination in so decided a manner, it would be an insult to him, and would make the society a laughing-stock, if he were now asked to come back.

Mr. HART concurred with Mr. Bird.

Mr. HOOPER, while thinking it was the duty of the society to retain its present officers until the end of the session, held that its interests were paramount to those of any one gentleman, whoever he might be. He certainly understood that the members proposed at the last meeting were elected to form a council, and the society ought to retain them as it then decided. If the president felt he could no longer hold his office, he should be allowed to retire with becoming grace and dignity.

Col. WORTLEY then asked that the minutes be read, and the business of the evening proceeded with.

Mr. BADEN PRITCHARD, who had signified his intention of resigning his office of secretary, consented to act temporarily, and accordingly read the minutes of the annual general meeting.

On the CHAIRMAN asking the meeting to confirm the minutes,

Col. WORTLEY took objection to their accuracy in respect to the following paragraph:—"Mr. Hooper moved the following resolution, of which he had given notice: 'That the president, vice-presidents, treasurer, council, and secretary be requested to resume office for the remainder of the present session, and that at the next annual meeting all officers be elected in accordance with the new laws about to be framed.'" Col. Wortley observed, with reference to this, that he had tied Mr. Hooper down to name thirteen members of the council and two vice-presidents, but this was not noticed in the minutes.

Mr. HOOPER said his motion was printed before the meeting was held, and therefore there could be no mistake.

After a remark from Mr. F. HOWARD, to the effect that both gentlemen were right,

Col. WORTLEY asked how it was there had been no Journal that month?

Mr. GOSLETT said he had never been summoned.

Mr. F. HOWARD, in reply to Col. Wortley, said the first letter sent to the council was to ask them to resume office. Since then no communication had been sent. The first was sent so that they could do as they pleased.

Mr. J. HUGHES's impression with regard to the minutes was that they were correct. Col. Wortley certainly challenged Mr. Hooper to name the council separately instead of generally, but the motion was put from the printed copy, which was identical with the circular sent to every member.

Some further discussion followed. Col. WORTLEY expressing his intention to press for a division. Eventually a motion as to the correctness of the minutes was taken, and was carried with but one dissentient.

The CHAIRMAN then suggested that it would be as well if the present position of the society were considered. To do that properly, he would propose the holding of a special meeting, so that the government might be placed on such a footing as would ensure the business of the current year being carried out. If the

meeting would trust in him, he would see that the necessary notices for holding a special meeting were given.

Mr. HUGHES having spoken to a similar effect,

Mr. STILLMAN said he thought nothing could be done until it was known whether the council had any authority or not to call the meeting.

Mr. SPENCER observed that the gentlemen who had resigned had only done so individually; the majority of the council still remained, and as they were relieved of the conditions to which they had refused to accede, the six gentlemen elected would be in the place the society intended them to fill. Unless it lost its self-respect, the society must stand by those gentlemen.

Mr. HOOPER reminded the meeting that of the eighteen gentlemen who formed the council, three only had retired, so that the affairs of the society could still be carried on.

Mr. STILLMAN thought the members ought to know how the council was constituted before anything could be done.

The CHAIRMAN observed that Mr. Glaisher had taken his own action in the matter, but that action would not affect the future proceedings. As Mr. Glaisher would not have the issuing of the notices, the matter need not be discussed any further.

The subject then dropped, it being understood that the chairman would take steps to call a special meeting for the purpose of discussing the affairs of the society.

A paper, written by Mr. George Bruce, of Dunse, on "Collodio-chloride Printing on Paper," was then read by Mr. Pritchard, and specimens submitted.

The CHAIRMAN observed that immediately after Mr. Simpson had described the process, Mr. Bruce took it up, and had from time to time exhibited some excellent examples, one of which, at the recent photographic exhibition, excited considerable attention. It was, perhaps, a little disappointing that the method of preparing the paper was not divulged, as Mr. Bruce used Ohernetter's paper. Of course some portions of work must necessarily be delegated to commerce, still it was always better if the experimenter could know the exact nature of the materials he used.

Mr. HOOPER had had some experience of collodio-chloride in printing transparencies, both in the camera and by contact, and nothing could answer better. As albumenized printing was becoming every day more troublesome, he should be only too glad to see another process which should be more permanent take its place.

Mr. WHITFIELD had not found collodio-chloride pictures, even when the film had been floated on to ivory, more permanent than albumenized ones.

Mr. S. DAVIS observed that he tried the process soon after Mr. Simpson had made it known, but had found great difficulty in toning. The pictures were of a rich brown when removed from the printing frame, but after toning the image seemed to sink into the paper, and became of a bluish colour. To obviate the sinking of the image, he had tried some albumenized paper treated with the collodio-chlorized solution, but still the difficulty of toning was not surmounted. He thought more investigation into the character and composition of the paper used was needed before the process could be made practicable.

Mr. B. J. EDWARDS had found the prints tone easier after immersion in alcohol. In regard to permanence, his experience coincided with that of Mr. Whitfield; besides which there was the liability to injury on account of the abrasion of the surface caused by handling.

Mr. HART, as a manufacturer of albumenized paper, believed that the reason why collodio-chlorized paper was not made in England was on account of the methylated alcohol necessary to its manufacture. Such a vapour as was given forth was most injurious to breathe. As to the instability of albumenized prints, he thought that if the hyposulphite solution were made alkaline, and used not more than ten minutes after it was made, there was little fear on that score.

Mr. J. HUGHES had made a great number of experiments with collodio-chloride. In using leptographic paper his conviction was that the prints were more permanent than those on albumen; as to their superiority in beauty there could be no question. He had also tried various samples of Ohernetter's paper, including some which he had procured from Mr. Bruce, but had got involved in all sorts of troubles. On paying Mr. Bruce a visit to see his method of working, he found the process necessitated an amount of care and labour which would prevent it being used by unskilled hands, such as were now employed by photographers. His experience of the process was, that it was most uncertain in all its stages.

The CHAIRMAN thought there was so much that was interesting

in the subject that it might well form matter for discussion at a future meeting. He would suggest that, as M. Obernetter would exhibit at the meeting of the 12th May some negatives reproduced by the powder process, it would be a good opportunity for renewing the discussion.

A vote of thanks to the chairman then terminated the proceedings.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

The fifth popular meeting of the season was held in Queen Street Hall, on Wednesday, the 8th inst.

The exhibition consisted of a series of pictures from negatives taken by Mr. John Thomson during a six-years' tour in China.

Mr. Thomson gave an interesting descriptive lecture, containing much information about the laws, manners and customs, &c., of the Chinese.

If the pictures and lecture are fair specimens of the illustration and matter of the book now in course of publication by Mr. Thomson, it will be a most valuable contribution to our knowledge of China and the Chinese.

### Talk in the Studio.

**CERAMIC PAINTING.**—We have frequently received enquiries on the subject of enamel painting, in reply to which we have been able to supply only very scanty information. We have just received a little work which will meet the purpose of all such enquirers. It is a treatise on painting china, glass, enamel, &c., by Mons. A. Lacroix, published by Leclertier, Barbe, and Co., 60, Regent Street. It contains full details of preparation of colours, fluxes, manipulation of the colours, burning, &c., and suggestions of various kinds which will be welcome to the worker in ceramic photography.

**SECOND-HAND APPARATUS.**—Mr. Morley has just issued a priced catalogue of a very large stock of second-hand lenses and other photographic instruments, including many by first-rate makers, which will interest many readers.

**INDECENT PRINTS.**—Mr. C. H. Colletto, solicitor to the Society for the Suppression of Vice, attended before Mr. Bridge to support a summons against Henry Hayler, of Pimlico Road, calling upon him to show why no less than 130,248 obscene photographs and 5,000 slides should not be destroyed, they having been seized by Inspector Harnett and Detectives Chamberlain and Marshall, of the E division.—Giles, the summoning officer, proved that no one had been on the premises for a week, and he had not been able to serve the summons.—Mr. Bridge, after carefully looking into the Act of Parliament, was of opinion that he was in a position to make the order for the destruction of the things seized in the absence of Hayler.—Mr. Colletto said the man could appeal against the destruction in seven days if he chose, but there was little chance of his running into the arms of the law. There were six cart-loads of the things. It was one of the grossest cases he had ever had anything to do with.—*Telegraph.*

**A NOVEL MARRIAGE.**—The *St. Louis Globe* says:—"The other morning Justice Jecko was called upon by a gentleman who requested the judge to accompany him to the photograph gallery of Mr. A. T. Urie, corner Forth and Market. The judge, with his usual urbanity, went. On arriving there, he found a young gentleman and lady from the lively town of Odin, Illinois, about to have their pictures taken. After the photographer had completed his task, the judge was informed that they wished to be married, whereupon the justice requested them to remain standing, and then, with the mellowed rays that came through the overarching skylight falling full upon them, and with the camera-obscura, like a mountain howitzer, pointed directly at them, pronounced the solemn and impressive words that united them for life. Mr. A. T. Urie officiated as master of the ceremonies, discharging his onerous duties with great grace and suavity of manner. The names of the happy couple are David Bugh and Julia Huddleston."

**EMBRACING A PHOTOGRAPHER.**—A FUNNY STORY.—Salvini, the actor (says a Toronto paper), when having a photograph taken, was so delighted with the proof that he flung his arms about the operator and embraced him. This was gratifying to the operator, and did not cost Salvini anything. A gentleman in this place, whose name we will not mention, was very much pleased with the great actor's artifice—as he

persisted in terming it—and, believing that appreciation is dearer to a true artist than money, he concluded to have some photographs of himself. When the proof was shown him he knew that was the time to fling his arms around the operator, but he could not pluck up sufficient courage. He thought he would wait a more favourable opportunity, and became very nervous in consequence. Pretty soon the operator had occasion to reach under a case of specimens for a cloth, and, full of desperation, shut his eyes and swooped down upon him. The frightened artist, believing that this was a new process for garrotting, straightway screamed murder, and sought to defend himself until the arrival of aid by beating the assassin over the face and head with a brush full of varnish. Every lick of the brush developed additional ferocity in the face of the customer, and consequently increased the terror of the operator, whose shouts aroused the inmates of the building, and brought to his help in quick succession a tailor, two dressmakers, four clerks, and a one-legged basket-maker. The benumbed and varnished victim was quickly overpowered, and, being sat upon by as many of the masculines as could be accommodated, was firmly held until the arrival of an officer. Fortunately, he was known by the officer, who recognised him from his apparel—not being able to see his features for the varnish—and, upon explaining that the cause of his coming down upon the operator was a sudden dizziness he experienced, he was released. A hack was obtained, and he was taken home, and his head put to soak in lime-water, for the removal of the varnish from his face. But it was found necessary to shave his scalp, as it was impossible to save his hair. He is glad now he got the pictures when he did.

**PHOTOGRAPHING COLOURS, AND FORGERY.**—A correspondent sends us an extract from the *Melbourne Argus* containing some curious details on the subject of photographing coloured surfaces in relation to bank-note forgery by photography. Mr. Perry, a Melbourne photographer, makes a claim of a discovery which enables him to defy the intervention of varied colours as a check to forgery. Having sent to the editor of the *Argus* a copy of a bank-note, he says:—"I think I may fairly say, without egotism, that the process by which this note has been photographed is entirely my own invention; I have never read or heard of the preparations it requires having been used before. The ingredients used are of such a nature as not to bring them under the notice of a photographer in his ordinary practice, and it is not likely that they would be easily discovered unless his studies were directed to chromo-photography. It is this fact which induces me to withhold the publication of the process, for should it become generally known, I fear it would be fraught with danger to those who repose on the fancied security of blue and coloured bank-notes." The *Argus* adds:—"A photograph (on a reduced scale) of a Union Bank note has been shown to us by Mr. Perry. It is a negative from a note printed in blue and other colours, and the artist has found no difficulty whatever in obtaining a faithful copy by a process which he has discovered. Mr. Perry has also shown us a negative of the same note obtained by the usual means employed by photographers, and the difference between the copies is remarkable. The artist informs us that, from the negatives he has obtained, notes can be reproduced in any colour or colours. The use of blue ink in note-printing, therefore, is no security against photographic forgery."

**RETOUCHING NEGATIVES.**—A correspondent of our Philadelphia contemporary says:—"Apropos of retouching, I wish to mention to you a method which succeeds remarkably well with me in the correcting of very weak negatives. I commence by printing from the defective negative a positive on paper, and then from that positive a negative also on paper. I fix without toning it, and then, whilst still wet, I place it on the back of the negative, to be corrected in such manner as to make the outlines of the picture coincide, viewed by transmitted light. I allow it to remain until perfectly dry and smooth, then with an ordinary pencil I perform by transmitted light the retouching necessary to increase the brilliancy of the lights, and by the means of varnish I render transparent those parts which I wish to make darker in the print. Printing with negatives prepared in this manner requires more time, but the effect obtained compensates for it with usury. Other merits of this process are the facility of retouching and the greatly softening effect which this prevents, owing to the diffusion through the glass which is between the two negatives."

To Correspondents.

**ARCHER CLARKE.**—Copyright in an engraving continues during twenty-eight years from the date of publication.

**POSTMASTER.**—There is always some little risk in pulling in and taking out wet plates from boxes, and care is the chief aid to immunity from tearing the film; but it is important to use suitable boxes, the grooves of which should be V-shaped. With such grooves and proper care no serious risk need be incurred. We believe that the majority of plate boxes now used have such grooves. 2. It is very difficult indeed to obtain a good copy of a mounted photograph, especially a small one like a card portrait, as the texture is generally very coarsely apparent. In the first place the card to be copied should be rolled as smooth as possible; or, if it can be removed from the mount, let this be done, immerse it in water, and lay face down on a plate of glass, and copy it through the glass. This will materially remove the effect of coarse grain. The best light is a diffused light, reaching the card equally from all directions. 3. The collodion in question is of a horny texture, and very apt to repel the bath. Probably some of the solvents have evaporated and made it thick. Add a little alcohol, which may possibly remedy the defect. An old developer loses its developing quality. 4. We fear that you will not be able to obtain Bigelow's Album from any library.

**F. M. M.**—We fear that there is no efficient method of repairing a cracked porcelain bath. Somewhat depends, perhaps, on the extent of the crack; if only slight, you might try to run marine glue into the crack.

**PUZZLED.**—We have very repeatedly given full instructions for producing enlargements by almost every method, both in the NEWS and YEAR-BOOKS. Perhaps one of the simplest complete statements of detail for several enlarging processes is that contained in a little work recently issued by Mr. Solomon, entitled "Photography in Four Lessons." Regarding the process you speak of having tried, we cannot, of course, tell in what point you have failed, unless you describe to us precisely how you carried out the operations. How, for instance, did you sensitize the paper? What paper did you use? What kind of negative, what extent of enlargement, and what kind of light did you try? It is always necessary to give a detailed account of your operations to enable us to point out probable causes of failure.

**OYSTERS.**—The cause of matt silver or oyster-shell markings is so various and complicated that it is quite impossible to discuss them fully in this column; but, as a subscriber, you are doubtless familiar with the fact that we have written many articles on the subject in back volumes, in which we have discussed the various causes and remedies. The most common causes are the use of a horny, repellent collodion, and the use of dark slides, or inner frames of dark slides, not perfectly clean. Age will modify the character of the collodion, and sometimes the addition of a few drops of water per ounce will effect a cure. The collodion you mention, although in most respects a very excellent collodion, is somewhat prone to this defect. Immersing the plate before it is thoroughly set as usual will also effect something. Let the plate rest on clean strips of blotting-paper, using fresh pieces with every plate. Be sure and wash well and frequently the inner frames.

**VOLEO.**—A tendency in collodion to produce the negatives lacking density may proceed from many causes. One of the most common is the use of insufficient pyroxyline. The addition of a grain or two of pyroxyline per ounce will often make all the difference between weakness and vigour in the negative. Some samples of pyroxyline will give vigour with three or four grains per ounce, whilst others require eight or ten to be employed to secure equal vigour. Then the quality of the pyroxyline very materially affects the question of density. But the conditions for making a suitable pyroxyline could not be discussed in the space devoted to this column. The proportion and quality of the iodides and bromides also affect density. Iodide of potassium or of ammonium, for instance, tends more effectually to produce density than the cadmium salts. The age of the collodion affects the question; a newly mixed and iodized collodion will often yield a thin image, and in a month or two will give density.

**JOSEPH PEACH.**—We fear that very few photographers would be willing to pay anything for the plan of mounting in question, but you can test it by advertising. Hermetically sealing a picture would not preserve it from change if it had the elements of change in itself, either from imperfect fixation or imperfect washing. The only mode in which you can test the willingness of photographers to pay anything for the information, that we can see, is to advertise the information for sale.

**E. L. P. T.**—We fear that varnish once applied to paper prints will not be very easily removed. The only mode in which it can be effected will be to soak the print in the solvent employed in the varnish. If a spirit varnish, soak in spirit; a succession of fresh baths of spirit may do something. If a benzole varnish, use benzole. But it is probable that the varnish may have permeated the fibre of the paper, and will be very difficult to remove. When it is removed, there is no effectual method of restoring a fading photograph.

**OXONIENSIS.**—The part played by copper in the developer is not well understood, but practical benefit seems to result from its use, and we see no objection to its use in cases of long exposure, nor to the use of the formula you name. 2. For long exposures, especially in warm weather, we think the addition of a little water is often beneficial to many collodions, and the first you mention especially, which, whilst very excellent, is somewhat horny and repellent. We are not in a position to give efficient advice as to which of the two collodions is best for interior work, as it some time since we used the latter. 3. We have published all the suggestions for the avoidance of matt silver stains which we know; but it would be difficult to recapitulate them here. Suitable non-repellent collodion, addition of water, hasty immersion, clean inner frames, clean blotting-paper on corners, weakening silver bath, adding bromide to collodion, adding a little glycerine to bath, adding nitrate of potash to bath, bath in good condition—these are amongst the most important hints for prevention and cure.

**UNCLE SAM.**—The owner of a copyright photograph must fill up a form duly describing it, and all details as to ownership, to Stationers' Hall, and pay therewith a shilling to the Registrar, who duly enters the particulars. If you have access to our YEAR-BOOK for 1863 you will find the Copyright Act, and all particulars relating to securing its provisions, there published.

**THOMAS ERWIN.**—Your cards generally are good. No. 3 is a little flat from over-intensifying; No. 5 thin and under-exposed; No. 6 a little lacking in definition; No. 7 under-exposed. On the whole, the work, as ordinary commercial work, is a fair average.

**A. G. W.**—Your failure is chiefly due to under-exposure. The negative you forward should have had at least twice the exposure. It is slightly under-exposed even for a collodion positive, and a negative, as a rule, requires two or three times the exposure of a positive.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR MARCH.

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 35 feet above sea level.

Date.	Morning.	Noon.	Night.	Direction of Wind at 9 a.m.	
1	10°	50°	43°	S.W.	Rain at night.
2	43	48	40	S.E.	Fair all day. Hazy and gloomy.
3	46	18	40	S.W.	Fair all day. Sunny.
4	42	48	43	S.	Fair all day. Foggy and gloomy.
5	44	47	12	S.	Rain a.m. and p.m. Slight aurora.
6	41	48	31	E.	Fair all day. Slight auroral light.
7	41	49	36	E.S.E.	Fair all day. Very bright.
8	42	48	36	W.	Rain at night.
9	41	48	36	E.	Snow showers this afternoon.
10	30	36	33	N.	Snow showers a.m. and p.m.
11	28	38	36	E.	Fair all day. Stormy.
12	42	—	—	N.W.	Snow early this morning. Showers of rain p.m.
13	40	49	44	N.W.	Fair all day. Gloomy.
14	41	49	47	N.W.	Fair all day. Gloomy.
15	40	46	46	N.W.	Fair all day. Gloomy.
16	46	48	41	S.W.	Rain a.m. and p.m.
17	41	48	46	S.W.	Fair all day. Gloomy.
18	16	50	40	N.W.	Fair all day. Sunny.
19	42	48	40	W.	Rain a.m. and p.m.
20	42	50	46	S.W.	Heavy hail shower early this morning.
21	42	18	44	S.W.	A little rain a.m. and p.m.
22	44	51	47	W.	Rain a.m. and p.m. Heavy a.m.
23	48	48	47	S.	Foggy all day.
24	48	50	40	W.	Fair and sunny all day.
25	40	52	48	N.W.	Fair and sunny all day.
26	46	50	41	S.E.	Fair and sunny all day.
27	41	19	48	S.W.	Rain and strong wind a.m. and p.m. Swallows.
28	14	47	48	S.	Rain and strong wind p.m. First butterfly.
29	50	50	46	S.	Rain a.m. and p.m.
30	49	50	48	S.W.	Rain a.m. and p.m.
31	48	49	46	S.S.W.	Fair all day. Gloomy.

We arrive at the following from the above data:—

	Mornings.	Noons.	Nights.
Maximum temperature during the month	50°	52°	48°
Minimum ditto ditto	28	36	34
Mean ditto ditto	42·9	48·2	42·7

Number of days during the month on which no rain fell ... 15  
 Number of days during the month on which rain fell ... 16  
 Number of fair days on which it was gloomy ... 7  
 ditto ditto ditto sunny ... 8

**EARLY VISITORS.**—Owing to the exceptional mildness of the weather, the swallows (*Hirundo rufa*) have this year made an unusually early appearance. They were observed on the 6th April in 1872 and 1873, while this year they were seen on March 27th. A butterfly was seen on the 28th.

April 2 1874. Wind from N.W. and S.W. prevailed.

## The Photographic News, May 1, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO LORD LINDSAY'S PHOTOGRAPHIC PROCESS—THE VOIGTLANDER GOLD MEDAL—A NEW PHOTOMETRIC RECORDER —PHOTOGRAPHIC JOURNALS ON THE CONTINENT.

*Lord Lindsay's Photographic Process.*—It is probable that the starch dry process will be the one selected by Lord Lindsay and his chief photographer, Mr. Gill, for the Mauritius transit of Venus expedition, some very favourable results having been already obtained with the method. The collodion plate is sensitized in the ordinary manner, washed two or three times, and then coated with a thin solution of starch, which dries, and forms a most stable protective to the sensitive film. Before development it is simply moistened in distilled water, and then treated with alkaline or acid developer, as may be desired. The starch gives great stability and strength to the film, which will resist a very great degree of mechanical friction without being injured; moreover, no risk of expansion or contraction of the image is to be feared when the film has been thus treated. Lord Lindsay anticipates starting from this country next month, although the expedition may, unfortunately, be delayed by the accident to the lens to which we have already referred, the extent of damage being greater, it turns out, than was at first hoped. Fears are entertained whether Mr. Dallmeyer will be able to make good those portions of the lens which have been broken, for although the instrument has but a diameter of four inches (its equivalent focus being thirty-eight feet), the elaborate nature of its construction is beyond conception.

*The Voigtlander Gold Medal.*—It is gratifying to learn that the Vienna Photographic Society awarded to M. J. B. Obernetter, of Munich, the Voigtlander gold medal for 1873, for his process of multiplying negatives by means of the powder process. M. Obernetter not only suggested the useful application of the powder process in this direction, but worked out the application so thoroughly and effectively that we are told no difference can be observed between impressions taken from the original negative and from the duplicates. This is in great measure due to the fact that the duplicate negatives are produced direct from the original without the aid of a transparency, so that none of the vigour or detail of the original are lost, negatives producing negatives, and positives positives. As many as three thousand negatives M. Obernetter has already reproduced by these means for his own work, and this circumstance alone proves how really practical and valuable the process will be to all photographers. We do not know if any Voigtlander gold medal has ever been previously awarded, but certainly none has been given for the past four years with the exception of the one just referred to, and there can be no doubt as to the propriety of thus recognising the services of M. Obernetter, who in many other ways has advanced photographic matters. His success in working out the collodio-chloride process, and producing a good commercial paper of this character, as also the high excellence of his Lichtdruck pictures, are matters which ought not to pass uncared for.

*A New Photometric Recorder.*—Dr. Roscoe has communicated to the Royal Society the details of a self-recording method of measuring the intensity of the chemical action of total daylight. A constant sensitive paper is exposed by a self-acting arrangement for accurately known times, at given intervals, throughout the day. The insolation apparatus, stocked with sensitive paper, is placed in position either early in the morning or on the previous night, and by means of an electric communication with a properly-arranged clock the sensitive paper is exposed every hour during the day, so that in the evening the observer has only to read off in the ordinary manner the hourly intensities which have been recorded upon the paper during the day. In order to

estimate the value of the successive tints which have been thus secured, other records of known intensity are obtained for comparison. A duplicate arrangement of a clock and insolation apparatus is set going, by means of which disks of the constant sensitive paper are exposed each hour for successive known intervals of time, varying from two to thirty seconds. After an interval of an hour another set of disks are exposed for the same series of intervals, and series of insulations are repeated once every hour during the day. On unrolling at the end of the day the strip of sensitized paper which has served for the exposures, black disks showing where the paper has been stationary for the hour are seen, and between each of these are found ten circles variously tinted, ranging from one, scarcely visible, representing two seconds' exposure, to that which has been darkly coloured by an exposure of thirty seconds. Amongst these, one will be found of a shade to enable it to be read off by the monochromatic soda flame, on a graduated fixed strip, as Dr. Roscoe has explained in previous communications. The manner of preparing strips or rolls of chloride paper of constant sensitiveness is explained in Dr. Roscoe's paper, as also other practical and important details.

*Photographic Journals on the Continent.*—The two German photographic journals, *Licht* and *Helios*, have now ceased to exist, the former being the organ of the Berlin Photographic Society (not the Berlin Society for the Advancement of Photography, be it borne in mind), and the latter being the organ of the Dresden Photographic Society, whose president and editor, Dr. Krone, is commissioned to proceed to the Auckland Islands to observe the transit of Venus on behalf of the German Government. Germany is still, however, well represented by photographic journalism, there being no less than four periodicals still in existence: the *Photographische Mittheilungen*, the *Photographische Archiv*, the *Photographische Correspondenz*, and *Photographische Notizen*. The two former are North-German publications, and the two latter Viennese. France has two periodicals devoted exclusively to photography; and Belgium, Holland, and Italy, one each respectively.

### ON PRINTING AND TONING COLLODIO-CHLORIDE PAPER.

BY GEORGE BRUCE, OF DUNSE.\*

THERE is not a doubt that if all the members of our profession aimed at a higher standard of negatives, there would be less boasting of the number of plates taken in a given time, and more thought and skill expended to make a few good ones. But it may be asked, "What about the exchequer? How can money be made by a professional photographer, and honourable retirement from business looked forward to, if we do not 'push the trade?'" All I can say in answer to this question is, that the taking of fine photographs cannot be thought of in the same way as a trade in groceries. What would Wilkie have given to some of his patrons, had he measured his work by the paltry sums of money he got from them? The gentlemen who made the terms would have been rightly served had the artist given them bare value for their money; but in doing so the world would have lost treasures of enduring delight, and the name of Wilkie as a great painter would have remained for ever unknown.

I believe that no photographer can devote sufficient time and skill to the execution of his work whose mind is constantly running upon £ s. d.; and while it is imperative that we should be able to live as well as merely to exist, yet our gain should not be secured by producing quantity so much as quality, charging in ratio to the efforts put forth.

The photographs I sent to the Exhibition were, as I said before, printed upon collodio-chloride paper prepared

\* Continued from page 195.

by Herr Obernetter, of Munich. That gentleman has supplied this paper to photographers for some years past; and as ever since he began to manufacture the material I have used it, I have acquired considerable experience in working the material.

For the first year or two I found great difficulty in printing my work upon it; but the faults inherent to the paper at that time, such as the tendency of the film to peel off when the prints were immersed in water; the hard, horny character of the film itself, which cracked so easily that it was next to impossible to pass the prints through the toning and fixing baths uninjured; the want of sufficient silver on the film to give depth and richness to the shadows—these have been entirely overcome. The material now sent me is on the whole very good, although in some samples the paper on which the film rests is too thin to support it, so that when the prints are wet they curl up into tubes, and consequently require more care and skill in handling to get good pictures than they do when the film rests upon a thicker basis.

To show, however, that good prints, free from stains and cracks, may be secured upon the thinnest sample of collodio-chloride paper, I may mention that the photographs exhibited by me were printed on such samples.

In dealing with this paper I avoid printing too deep—that is, scarcely so deep as when using albumenized paper, as the prints lose but little of their depth in passing through the fixing bath. The paper requires great care in handling. When cutting the sheets ready for printing upon, and when examining the progress of printing when in the frames, I find that the finger touching the sensitive surface for a moment is sure to cause a stain when you come to tone the prints. The paper will keep good for days between printing and toning—a property, no doubt, useful at times, when one is busy and cannot get the day's work toned at night, or when dull weather sets in and printing goes on slowly. I am impressed, however, with the idea that this merit in prepared sensitized papers should be taken advantage of as seldom as possible, as I am convinced that the taking of silver prints out of the frames, and laying them aside for days or weeks before finishing, is an arrangement not conducive to improve their appearance, but rather the reverse.

It is, I believe, generally admitted that a wet or dry plate cannot be developed too soon after exposure; and if this holds true with sensitized plates, the same follows with sensitized silver paper when once the light has acted upon its surface. This being my opinion, I do not care to keep my prints any longer than need be before they are toned.

My toning bath is made as follows:—

Stock Solution. No. 1.	
Sulphocyanide of ammonium	... 1 oz. 2 drs.
Distilled water	... 50 ozs.
Stock Solution. No. 2.	
Gold	... 35 grains
Distilled water	... 50 ozs.
<i>Fixing-bath.</i> —Hyposulphite of soda	
	... 5 ounces
Distilled water	... 30 "

The gold I use for toning is prepared according to Col. Stuart Wortley's formula, given in the YEAR-BOOK for 1871, page 91, and it gives in my hands more uniform results when toning collodio-chloride paper than I ever obtained with the ordinary commercial samples of chloride of gold. Why I cannot tell, any further than that in preparing your own chloride of gold you know exactly what you have at hand, and the strength of the toning bath is more under your control. This "control" is absolutely necessary to success with collodio-chloride papers, as I find that anything more than the strength given in the formula produces a flat, eaten-out picture, without any depth; while, on the other hand, too weak a toning bath gives heavy, opaque brown tones. Thus, if

the toning goes on too quickly, you lose depth and richness; if very slowly, a brown, leathery tone is produced, which is far from satisfactory.

The reason in the first case is, that the prints pass so rapidly from brown to black, that before you can well get them removed from the bath the point where richness lies is often lost. And, in the second place, the sulphocyanide of ammonium solution in some measure destroys the transparency and purity of the prints when they are left too long in contact with it. Particular care and attention must therefore be given to the toning bath, so as to have it neither more nor less than the strength stated, as collodio-chloride photographs are much easier stained in toning than prints upon albumenized paper; and, when unequal toning does take place, it is more visible in the former than in the latter.

In making up a bath, equal quantities of No. 1 and No. 2 are mixed, plenty of chalk being added, letting the whole stand for from three to five hours before use. With some samples of this paper the bath can be used at once; but with other sheets this is not the case, a deposit of gold taking place over the whole prints, and destroying the purity of the whites. It is better, therefore, to err on the safe side, by making up the bath a considerable time before it is required, and thus be assured of having a uniformity in one's photographs.

When I have many prints to tone I use two flat dishes capable of holding (say) a dozen prints each. I filter the solution into these dishes to the depth of one-fourth of an inch; were the liquid deeper the prints would not keep flat.

I wash in three changes of water; and as the prints generally curl up into tubes, I open each of them separately in the water, so as to get the surface uniformly washed. If this is not done, and done in each separate dish of clean water, uneven toning will be sure to take place. When the prints have been properly washed with a quick but gentle movement, I open up each picture and lay it flat in the bath face downwards; and when the dish is full I begin at the first and turn it over, brushing the face with a camel's-hair brush, and continue the process until the whole have been so treated, afterwards turning them back again into their former position, and so on without cessation, until the prints are ready to leave the bath. When stains occur in the course of toning, lift the print out of the solution, dip the brush in alcohol, and rub the spot slightly. Then immerse the print again, when it will be found that the stain has disappeared and the print has been saved.

When fixing the prints the same care is required in laying them separately in the fixing solution, turning them over, and keeping them in motion until they are fixed, which is completed, when the fixing bath is new, in two or three minutes.

When removed from the bath, the prints are immersed for a few minutes in three or four changes of water, and put under the tap for an hour or two. The water is then shut off, and they are left all night and throughout the next day until the afternoon; the water is changed now and again. The prints are then trimmed and mounted.

The system in use amongst many of the profession, of cutting the prints to the exact size wanted before turning them, cannot be readily adopted with collodio-chloride pictures. In their case the paper should always be a little larger than is necessary, allowing not less than one-eighth of an inch to be cut off all round after the prints have been toned, fixed, and washed. The reason for this is that the edges of the prints are very curly, and the film becomes frayed in the course of washing; by cutting away this frayed curly part, they are more easily and neatly mounted. As it is impossible to lay these prints upon blotting-paper and dry them in a flat state without cracking the surface, another method has to be put in practice for the purpose of trimming them. I use a piece of thin plate glass cut to the exact size of what the carte-de-visite

print should be, the edges being ground and the corners slightly rounded, so as not to scratch the picture. If the prints are more than ordinarily curly, I open them *underneath* the water, and lay the sheet of glass upon the face, and then lift both of them out of the water at once, the moisture between the two enabling me to move and adjust the glass over the print with the greatest ease. I then with a pair of long-bladed scissors cut along the four edges of the glass, and thus secure a straight clean-cut print without damaging the surface of the photograph.

The medium I use for mounting is starch, carefully boiled, as thick as possible. It is, while still warm, poured into the centre of a muslin cloth, the corners of which are drawn together and held firmly with the left hand, while the right hand presses the bag and causes the pure starch to exude through the interstices of the cloth—the result being a paste perfectly free from gritty matter, and of the right consistence for mounting. A sheet of thick plate glass is covered with a damp cloth, and the prints are lifted from the dish and laid upon it in a wet condition, the water on the face of the prints and the damp cloth preventing them from curling. They are then pressed quite flat with another cloth, and dried before they are starched.

After the prints are mounted, dried, and spotted out, I roll them upon a hot steel plate; they are then put up in dozens into paper and laid upon the machine plate, and when warm are rubbed over with "Solomon paste," which gives them a richness and transparency they would not otherwise possess.

If desired, these photographs may very easily be covered with Mawson's print varnish or enamel collodion by coating them with a camel's-hair brush of the same breadth as the card. In my own practice, however, I rarely varnish the pictures, as I think they are more beautiful and artistic when simply finished with wax paste.

And now I have brought to an end my remarks on the production of collodio-chloride prints; but I cannot close this paper without expressing my regret that so valuable a method of printing, given so generously to the profession by Mr. G. Wharton Simpson, should have been so little practised amongst us, considering the beauty and delicacy of its results. I must also express my surprise that the manufacturers of photographic papers in this country should still leave those of us who wish to print our work by this process to get the material for the purpose from the Continent. The distance it has to travel has been, and must always be, a drawback to its general use, and especially in warm weather. Meanwhile, until a manufacturer be found in Britain who will make a first-class collodio-chloride paper, those desirous of trying the material may obtain it of good quality from Herr Obernetter, of Munich. As I am particularly anxious that this method of printing should have a fair trial, and past experience has shown me that it is of the utmost importance that the printer should receive the paper direct from the manufacturer (for only in this way is full justice done to both), I have written to Herr Obernetter, requesting him to supply small parcels to any gentleman desirous of making experiments in this direction.

#### SPECTRUM ANALYSIS AND PHOTOGRAPHY.

BY J. NORMAN LOCKYER, F.R.S.\*

In the year 1863 we have another equally distinct advance to chronicle, but this time the work is done in France. Mons. Mascart—a name very well known to physicists—undertook a tremendous work, which he has not yet completed, namely, a complete investigation of the ultra-violet solar spectrum.† Instead of using a quartz prism, as Dr. Miller had done before him, Mons. Mascart uses a diffraction grating—that is to say, an instrument by means of which the light

is not refracted, as in the case of the prism, but diffracted by an effect of interference of fine lines ruled on glass. Mons. Mascart has shown it to be possible, by means of reflecting light from the first surface of the diffraction gratings, to get light diffracted without its going through the glass at all. In this way, therefore, you avoid altogether the imperfect transparency of the glass. Professor Mascart has gone on advancing every year, until now he has completed a photographic map, not only of the solar spectrum extending about as far as the line R, by means of photography, but he has been able to observe as far as the line called T. There he finds the solar spectrum ends; but in the case of a great many vapours—such, for instance, as that of cadmium and other metals of the same nature—he finds he can go on photographing very much further, and has been able to photograph almost as far as the eye can see—that is to say, to a distance, as I have already told you, five or six, or even seven times as far from the line H as H is from A. So that you see, thanks to photography, we can now photograph six times more of the spectrum than we can see of it with the eye ordinarily.

Next come to a very beautiful reflex action of spectroscopy on photography; and now I must take you back to America. I am nearly certain that every one in this room is perfectly familiar with the name of Rutherford in connection with celestial photography, but if you will allow me I will point my reference to him by throwing on the screen one of his magnificent photographs of the moon, which he was good enough to give me some little time ago; and I am anxious to show this on the screen, especially to show you the wonderful skill of which he is capable. Unfortunately, I am not able to throw on the screen a photograph of the magnificent solar spectrum which we owe to him, the most magnificent photograph of the solar spectrum—and I say it with the intensest envy—which I think it is possible to obtain. However, I have a copy of it on the wall, and it is well worth inspection. Rutherford, whose name is associated with that of Mr. Delane with regard to celestial photography, was not content with the reflector, the very instrument by which this beautiful photograph of the moon, which I will show you, was taken. He lives in the centre of New York, and I suppose New York is almost as bad as London for tarnishing everything that the smoke and atmosphere can get at; and he came to the conclusion that he must either abstain from celestial photography altogether, or else make a lens—and a lens with Mr. Rutherford means something over 15 inches diameter—which should give him as perfect an image in New York with 15 inches of glass, as a perfect reflector of 15 inches aperture would give him as far away from a city as you please. Mr. Rutherford, who never minces matters, knowing that it was absolutely impossible to get such a lens as this from an optician, who of course neglects almost entirely the violet rays—the very rays which Mr. Rutherford wanted, when he makes an ordinary telescope, determined to make such an one himself. He thought about the matter, and he came to the conclusion that in any attempt to correct a lens of the magnitude of the chemical rays, the use of the spectroscope would be invaluable. He therefore had a large spectro-scope made, in order to make a large telescope, and then we have just as distinct an improvement upon the instruments which we owe to the skill of those who first adopted the suggestion of Sir John Herschel, and brought together the chemical and the visual rays, as the improvement we owe to Herschel was upon the instruments which dealt simply with the visible rays. Mr. Rutherford simply earts away the visual rays bodily, and only brings together the chemical rays; the result of his work being a telescope through which it is absolutely impossible to see anything, but through which the minutest star, down, I believe, to the tenth magnitude, can be photographed with the most perfect sharpness. This is the instrument of the future, so far as stellar astronomy is concerned. Having thus achieved what he wished in the construction of this instrument, and having the spectroscope, Mr. Rutherford commenced a most elaborate research, which, I am sorry to say, he has never published, for it would be of the greatest value to any photographer or any astronomer among us, upon every kind of collodion which he could obtain in America or in Europe, and upon every possible arrangement of lenses. Mr. Rutherford found that some collodions which he got were so perfectly local in their action, as to be almost useless for that reason, and that other collodion were so general in their action that they were also almost useless for the exactly opposite reason. I will now throw on the screen the line G and the lines in the green, or rather the lines approaching to the green near F: with ordinary collodions such as ours generally get—that is to say, collodions not absolutely good, but free from both the extremes referred to by Mr. Rutherford—we want something like

\* Continued from page 197.

† "Annales Scientifiques de l'Ecole Normale Supérieure," Vol. for 1864, page 219.

five seconds for the part near the line G. Well, when you go a little way along the spectrum in the less refrangible direction, you have to put minutes for seconds—in other words, the exposure has to be sixty times as long. I have another photograph of the spectrum, which will show you the part of the spectrum less refrangible than the line F to which I have referred. This photograph which you see on the screen now required very nearly half an hour.

Those of you who are most familiar with the solar spectrum will recognise the extreme importance of Mr. Rutherford's contribution to photographic spectroscopy, when I tell you that, in the opinion of the best judges, his photograph of the solar spectrum is quite as admirable and excellent as is the photograph of the moon which I have just shown you on the screen. During the last year this question of the solar spectrum has again been considerably advanced by photography in America. Mr. Rutherford's photographs, admirable although they are, are refraction photographs, that is to say, prisms were used, and more than this, prisms of glass. You will, therefore, quite understand that the photograph which you see extends only a very little distance beyond the lines H. But America was not satisfied with this, and in the person of Dr. Draper, the son of the Professor Draper whose name is so honourably associated with the commencement of work done in photography thirty years ago, Dr. Draper has just now photographed a solar spectrum far beyond H. A copy of his photograph is on the wall, but unfortunately I have not a copy which I can throw on the screen.

I have already referred to the extreme importance of photography in astronomy, and the point that I wish to urge to-night, after what I have stated regarding all the work which has been done up to the present time, is this. That what photography has been in the past to astronomy—what it will be in the future no one can say—such can photography, and such must photography, be to chemists and to physicists. Of course, in the way of photographic application, it is scarcely fair to say that a daily photographic record of the prominences around the sun is a question either of physics or of chemistry. But still the method which enables us, or which, I hope, will enable us shortly, to obtain a daily photograph of every prominence which bursts out—although absolutely invisible to our eyes—on the sun, is a method which depends on physical laws, and has nothing to do with astronomy in the ordinary sense. If you will allow me, I will show you now on the screen a photograph of a drawing which was made by an eminent Italian observer in India during the last eclipse. It is a drawing made by Professor Respighi, of the sun's corona, as seen by the spectroscope; and I hope in the next eclipse we shall not any longer have merely drawings to refer to, but that we shall have a photograph which can be bodily brought here, and which will let us know exactly how the matter stood. You see there on the screen three rings—a red ring, a green ring, and a blue ring. They are red, green, and blue, because the element in that part of the sun's atmosphere hydrogen gives us lines in the red, green, and blue; and they are rings because the hydrogen atmosphere extends in the most admirably regular way all round the sun. In fact, we may say, that in observations of this kind, we use the corona instead of the slit, and if that is good for the corona it is perfectly obvious to you it is good for the chromosphere—for the brighter regions lying closer to the sun than the corona does—as we know that it gives a line of such intense blue, exactly where photography, as it is generally carried on, has its strongest *point d'appui* in the spectrum; and it is quite clear to you that we ought to be able to get a photograph of this every day, just as easily as we saw it in India during the eclipse.

We will next consider the application of photography, no longer to the mere solar spectrum, but to the physics of the sun. What is the solar spectrum? It is the continuous spectrum of the sun, minus certain portions where the light of the continuous spectrum has been absorbed. What have been the absorbers? The gases and vapours, generally speaking, in an excessively limited zone of the sun's atmosphere, lying close to the bright sun we see; close, I say, to the photosphere. This zone is called the reversing layer. Then if the solar spectrum is the result of the absorption of this reversing layer, what will happen to the solar spectrum if the constitution of the layer changes? Obviously a change in the solar spectrum. Now, recent researches carried on by means of photography show us that if you take any particular vapour in the reversing layer, which you may call A, for instance, and then assume that the quantity of A in the layer is reduced, the absorption of that particular vapour will be reduced; what then will be the result on the photograph of the solar spectrum? Some of the lines will disappear. Suppose that this particular

vapour which we call A, instead of being assumed to decrease in quantity increases in quantity, what will happen to the solar spectrum? The same researches have told us that as its quantity increases its absorption will increase, and that its increased absorption will be indicated by an increase in the number and in the breadth of the lines absorbed. What, then, will happen to the solar spectrum if any change of this kind is going on? The photograph of a solar spectrum taken, say, to-day, may be different from the photograph of the same part of the spectrum taken at some distant period. What is the distant period we do not yet know—whether three months, six months, six years, or eleven years; but, at all events, there is reason to think already, that if we had a series of photographs of the solar spectrum, taken year by year, that we should see very great changes in the spectrum. Allow me to show you a photograph of a very limited portion of the solar spectrum, and I will prove my case; and let me tell you I could not prove my case if photography had not been called in because if the existence of any particular metal, or of the increase of any particular metal depends on such a small matter as one line among 10,000, what will happen if a man neglects to observe this change? People will say, "Oh! in a research of that kind it is altogether excusable if he has made a mistake." But if you have a series of phenomena recorded by means of a camera on "a retina which never forgets," has Mr. Delarue has beautifully put it, and if you compare those pictures day by day, and year by year, the thing is put beyond all question when you get one line disappearing, or another line appearing.

Now we have before us a part of the solar spectrum near the line H, and I wish to call your particular attention to one line. We have admirable drawings of the solar spectrum taken about the year 1860. If the draughtsman was recording by means of his eye the lines in the spectrum, he would not be very likely to overlook a line darker than some he inserts, but he might easily overlook finer lines. Now, it is a fact that in the most careful map that we have—a map drawn with a most wonderful honesty and splendid skill—a line is absent in the region indicated, which line is now darker than some that were then drawn, and that line indicates the presence of an additional element in the sun—strontium. I do not make this assertion thinking that subsequent facts will show the drawing to be wrong, but because I see reason to believe that what we know already of the sun teaches us that it is one of the most likely things in the world that strontium was not present in such great quantity in the reversing layer when the drawing was made; but, however that may be, I think you will see how important it is that this photograph, which I have just thrown on the screen, should be compared with photographs made five, ten, fifteen, a hundred, or two hundred, or as many years as you like ahead, and it is in this possible continuity of observation of the solar spectrum, carried on for centuries, that I do think we have in photography not only a tremendous ally of the spectroscope, but a part of the spectroscope itself. Spectroscopy, I think has already arrived at such a point, at all events in connection with the heavenly bodies, that it is almost useless, unless the record is a photographic one. I am glad to say that only to-day I have had a letter from Dr. Draper, who tells me he has at last succeeded in getting an admirable photograph of the spectrum of a star. Now that is of the very highest importance, because the sun is nothing but a star, and the stars are nothing in the world but distant suns; and as long as we merely investigate the sun, however diligently or admirably we do it, and neglect all the others, it is as if a man who might have the whole realm of literature to work at should confine himself to one book, and that book probably not a very good representative of the literature of the country he was examining into.

(To be continued.)

## THE COLLODIO-BROMIDE AND SHELLAC PROCESS.

BY J. F. PLUCKER.\*

THE collodio-bromide process is, without doubt, the simplest dry plate process, and yields results quite as beautiful as, if not more so than, the silver bath method. The preparation of the plates is a very rapid matter, and there is no silver bath necessary, a great advantage when large plates or enlargements have to be worked in the camera. The plates are developed very uniformly, quite clearly, and free from spots. In the case of objects which reflect many chemical rays, the sensitiveness is the same

as that of ordinary plates; on the other hand, where the reflected rays are weaker, as in the case of foliage, shadows, &c., the sensitiveness of the collodio-bromide plates is even greater than that of the ordinary wet films.

After many experiments with collodio-bromide prepared according to different formulæ, M. Plücker has succeeded, by the addition of yellow shellac to the mixture, in securing excellent results. His method is thus summarized:—

1. *The Bromide Collodion.*—In one hundred cubic centimetres of alcohol are dissolved two grammes of bromide of cadmium and half a gramme of bromide of ammonium. To this are added two and a-half grammes of pyroxiline and one hundred and fifty cubic centimetres of ether, then eight decigrammes of yellow shellac which have been dissolved in a water bath, and finally three drops of sulphuric acid. After this collodion has stood for some two or three weeks it is ready for use.

2. *Sensitizing the Collodion.*—About an hour before employing the plates the collodion is treated with nitrate of silver in the following manner:—Into a test-tube about twenty centimetres long and fifteen millimetres broad is put one gramme of finely powdered nitrate of silver crystals, together with four cubic centimetres of rectified alcohol and one drop of distilled water. This is carefully heated over a spirit lamp, and then poured into fifty cubic centimetres of bromide collodion contained in a wide-necked stoppered bottle. This sensitizing of the collodion must, of course, take place in the dark. The mixture is thoroughly shaken for some seconds, allowed to stand for an hour, and then poured into another bottle.

3. *Preparation of the Plates.*—The plates are treated in the ordinary manner with the collodio-bromide, a little ether being added if the solution pours too thickly. More collodion must not be sensitized than is required, for it does not keep good for any length of time. The amount just mentioned of fifty cubic centimetres is enough for twelve plates measuring 11 by 15 centimetres, or for two plates of 27 by 33. The plates, after being coated with the collodion, are washed with rain or distilled water, to free them from any free nitrate of silver that may be upon them. Then they are allowed to dry; or they may, before desiccation, be treated with tannin, dextrine, acetate of morphia, or any other of the well-known preservatives. As the collodio-bromide plates are very transparent, it is advisable to back the glass with yellow or black pigment (such as a mixture of lamp black, or dextrine), as in this way any reflection is prevented, and blurring of the plate provided against. Before development the pigment is removed by a wet sponge.

4. *Development.*—After exposure in the camera, the film is softened by pouring over a mixture of equal parts of alcohol and water. As much water as is necessary to cover the plate is put into a developing cup with a few drops of a fifteen per cent. solution of pyrogallie acid, as also a drop of a ten per cent. solution of carbonate of ammonia in water. When the image begins to appear, a little more of the pyrogallie and ammonia solutions are added until the details in the shadows are perfectly apparent. If the picture is not dense enough, it is intensified with silver and pyrogallie acid as if it were a tannin plate. If the shadows are a long time coming, more pyrogallie acid than alkali is added to the developer; if the exposure has been too great, then the amount of alkali is increased. A ten per cent. bromide of potassium solution in water will be found instrumental in preventing the fogging of the image.

## TWO PHOTO-ENGRAVING METHODS.\*

THE transformation of a photograph into an engraving block, from which engravings may be produced, is one of the great problems of the art; and upon this subject M. Gourdon has recently made some interesting researches.

\* *Année Scientifique.*

His observations are based upon a result discovered by M. Merget. This physicist found that zinc, when covered by a precipitated metal, is not open to the attack of dilute nitric acid, except in those places where it is bare; whilst, on the other hand, sulphuric, hydrochloric, and acetic acids, in a dilute form, only attack those portions covered by the foreign metal.

When covered up by certain metals, zinc alters with the greatest facility. If a sheet of zinc be coated in places with a film of pulverulent platinum, a film which may be produced by simply writing upon the plate with a solution of bichloride of platinum, the zinc will be open to the attack of sulphuric acid, diluted with seven thousand volumes of water, in those places where it is covered with platinum. If the latter be replaced by gold, the zinc may be dissolved by sulphuric acid diluted with 5,000 volumes of water. Then comes silver 3,500 volumes, tin 1,500 volumes, antimony 700 volumes, bismuth 500 volumes, lead 400 volumes.

Cobalt, nickel, and iron behave like platinum. Cobalt will determine the solution of iron in sulphuric acid diluted with 10,000 volumes of water.

The salts of the same base with different acids do not act in the same way. The chlorides give more energetic deposits than the sulphates, and these produce again stronger ones than the nitrates. Salts which produce no deposit, employed pure, furnish very active ones when they are treated with ammonia. Zinc covered with a metallic deposit is easily attacked, not only by acids, but also by alkalis in solution.

The presence of electricity is not sufficient of itself to explain these phenomena. Another cause, the porosity of the zinc, which is increased wherever active salts are placed upon its surface, must not be overlooked.

It is by taking advantage of some of these reactions that M. Gourdon has been enabled to elaborate two processes of helio-engraving, transferring a photograph into an engraved plate.

The first of the processes is the following:—In an ordinary photograph the image is produced by the deposition upon the paper of metallic silver. If we suppose a photographic print to be applied to a zinc plate, the silver transported from the paper to the plate, a metallic film will be produced, which will determine the etching of the zinc by an acidulated liquid. M. Gourdon employs cyanide of potassium to transfer the image to the plate. The paper print, on coming out of the printing frame, is plunged into a solution of hyposulphite of soda, and then carefully washed; it is then applied, face downwards, to the surface of the zinc. It is first moistened with ammonia, and a few moments afterwards with a solution of cyanide of potassium, either pure or mixed with carbonate of soda. After a time the silver will be entirely transferred from the paper to the zinc. This is accomplished with such uniformity that the metal bears exactly the same impression as that which was first fixed upon the paper. The plate is then etched with dilute acid, and the printing block is finished.

The second process is founded upon the property possessed by certain compounds employed in pigment or enamel printing to remain dry when sheltered from light, and to become hygroscopic if exposed to the sun's rays. These compounds are first spread upon paper; the portions which have become moist after exposure to light behind a positive or negative are then capable of retaining a powder sprinkled or brushed over the surface. This powder consists of certain metallic salts in a fine state of division, choice being made as to the kind of metal selected, according to the chemical reactions which have already been recorded by M. Merget as above described. The image covered with a saline powder is applied to the zinc by means of ammonia in vapour or in liquid. The image afterwards etched with dilute sulphuric acid gives, as in the former case, an engraved plate, from which engravings may be pulled by means of fatty ink.

## PHOTOGRAPHIC ENAMELLING PROCESSES.

THERE is, probably, no branch of photography producing results of such high excellence, which has made so little headway with the mass of photographers, as that devoted to the production of ceramic photographs. A fine photographic enamel is, as a rule, an embodiment of all that can be desired in a photograph. It possesses the delicacy of the Daguerreotype with the vigour of a paper print, and a peculiar softness without loss of definition, and a pearly tenderness in the minor lights rarely found in any other picture. And it is not only permanent, but indestructible, unless, indeed, it be crushed under a hammer, or melted in a furnace. And yet, although modes of producing such charming portraits have existed for nearly twenty years, the art is still in its infancy, and those who undertake its study may be counted by tens instead of tens of thousands.

The paper read by Herr Obernetter before the Vienna Society, which we print on another page, will aid in smoothing the way of many who have failed in producing perfectly satisfactory results with the powder process. As our readers know, there are three distinct methods of producing photographic enamels which have scarcely anything in common with each other. The three processes are—the tissue process, the conversion process, and the powder process. The tissue process consists in preparing a tissue like carbon tissue, using a ceramic powder in place of carbon or other pigment. It was suggested in our pages soon after the publication of Mr. Swan's process. A few years later Mr. Firling worked the process out, and we described the results in these pages. It has, however, never come into practice, and a few months ago it was re-discovered, and described as a novelty. The powder process is, in many respects, the most easy method of the three; it is more essentially mechanical than the others, and, in some respects, more completely under control than the others. And yet it is much less practised than the conversion process. We do not at the present moment know a single photographer in this country who practises the powder process, whilst there are perhaps a dozen practising the conversion process. The fact appears to be this; although there are many uncertainties in the conversion process, the results, when perfect success is attained, are infinitely finer than any other. It is not difficult, as a rule, to distinguish by which process an enamel has been produced. The image produced by the powder process rarely possesses the delicacy of that produced by the conversion process. There is a certain dull opaqueness in

the shadows, and at times a granular quality in the deposit, which contrasts very unfavourably with the translucent delicacy obtained by the other process. Whether equally good results can be produced by each process we cannot say, for profound secrecy is preserved by some of those who produce the finest results; but we believe that the most successful men use the conversion process.

Besides being inferior in delicacy, a variety of minor difficulties have beset the powder process, arising from the presence of the chromic salt. These difficulties Herr Obernetter has overcome, and as some of his results, which we saw some time ago, were exceedingly fine, we commend his paper to the careful consideration of those interested in producing enamels. In the powder process there are two or three advantages of the utmost importance. In the first place there is more complete control over the tone of the picture than in the conversion process. In the latter there is generally more or less uncertainty of the precise tone a picture will possess after it is burnt. In the powder process, if a suitable ceramic pigment has been chosen, it will generally burn to the precise tint for which it has been selected. The presence of chromic salt used to interfere somewhat in this matter, but, according to Herr Obernetter, this trouble need not be encountered again. The greatest advantage possessed by the powder process consists in the control which the operator possesses over the character of the picture, in applying the powder in greater or less proportion upon different parts of the image.

So far as we can see, also, the powder process should be most suitable for enamels for colouring. As a rule, a highly-finished enamel miniature undergoes several firings, and it is customary to apply those colours which require the greatest heat in firing first, and those which vitrify with a lower heat in regular succession, the heat at each successive firing being lower, so that the colours already applied are not affected by each fresh firing. With enamels produced by the conversion process this at times involves a difficulty, as it may be that some of the colours may require a higher heat than that at which the photographic image was fired. Yet some of the finest coloured photographic enamels we have seen are produced upon images by the conversion process. Mr. Lee, of Cardiff, recently patented a method of producing these pictures. The specification does not seem quite clear as to the point protected, but the method is clearly a conversion process. Whatever may be the point of the patent, the method employed is manifestly a good one, and the personal skill very great. The colouring is rich, brilliant, and natural; and as commissions are undertaken to place such personal skill at the service of photographers, the method is of less consequence.

As regards the early history of enamel photography, Herr Obernetter is scarcely accurate. He accredits the powder process to Mr. J. Wyard, in 1860. In April of 1860 a paper by that gentleman on the powder process was read at a meeting of the Photographic Society. But some months previous to that a similar process had been specified by Mr. Joubert at the English Patent Office, the process being the joint discovery of himself and M. Garnier some months before that in France. But it is very probable that M. Lafon de Camarsac knew the process several years earlier. In a paper in the *Comptes Rendus*, in 1855, upon enamel photography, written, apparently of set purpose, in vague and general terms, he refers to the production of a sticky image, to which enamel colours are applied, which adhere in due gradation. In like manner allusions are made which indicate a knowledge of the conversion process. How early attempts were made to burn in or seal up the ordinary photographic image by means of a vitreous varnish we are uncertain; but Mayall, Malone, Tunny, McCraw, Barnes, Scaife, Forrest, and others all experimented in this direction. The first successful conversion process appears to have been that of

MM. Marechal and Tessie du Motay, who patented a process in 1861, by which the silver image was treated with different toning solutions, platinum and gold being employed to produce a black tone after burning in the muffle. A couple of years later Herr Grune patented a similar method, but extending materially the number of metals and metallic oxides into which the image could be converted, or which might be deposited upon the image so as to produce different tones in the photograph after firing. Platinum, palladium, iridium, gold, iron, uranium, manganese, singly or in combination, were used, and it is from the publication of Grune's process that conversion processes may date their practical rise and progress. Since their invention there has been none in connection with the process, although the marvellous advance in results has been due to modifications and improvements in formula and manipulations. A week or two ago Mr. Watson wrote to us, complaining that his formula, sold under pledge of secrecy, was published without any recognition of the "inventor;" and this week a correspondent writes to ask if, having purchased a secret formula under pledge of secrecy, he has any remedy when the vendor of such secret formula openly publishes it. In each case there is, doubtless, a breach of contract; but it does not concern us to comment on the matter. The sale of a formula or method which has been arrived at by careful experiment is, doubtless, perfectly legitimate; but it is equally doubtless that it is beset with risks which must be accepted as a part of the bargain. And, as a rule, the vendor of a secret must content himself with such solid pudding as he may secure, credit of any kind, even if he really be an inventor, rarely accruing to the vendor of a secret. The novelty in Mr. Watson's case appears to consist in the use of a mixture of the chlorides of iridium and gold for toning the image. As such a mixture produces a fine tone not easily otherwise attained, it constitutes a decided improvement and good saleable formula; but it has no claim to invention. Ten years ago we referred to the use of a mixture of the chlorides of iridium and gold in toning prints; Tessie du Motay used a mixture of the chlorides of platinum and gold for toning enamels; and Grune refers to the use of iridium, gold, and other metals, singly and in combination. Mr. Watson's formula is, we believe, a good one, and we think that it aided various experimentalists as one of the stepping-stones to success; but it is important to distinguish between working out a good formula with materials already known and used for the purpose in question, and originating a new process so as to give a claim to the credit of invention or discovery.

#### A NEW NEGATIVE PROCESS.

tidings of an extraordinary new negative process reach us from Japan. A German gentleman named Hammenstede, dating from Yokohama, issues a circular announcing his discovery of a new negative process, for which he makes very remarkable claims. It yields, he states, infallible results, all the defects of negatives hitherto met with, being eliminated, and no silver bath is needed. The preparation used will keep good for years, is not affected by climate, and may be used to the very last drop. Dry plates prepared with the new material keep good for years. The exposure is more rapid than with the most rapid wet collodion plates; the cost is less than in the ordinary process, and it is more simple in manipulation than the ordinary process. Such, with some other minor advantages, are the claims made for this new process, the nature or details of which are not indicated further—except, indeed, negatively, for we are informed that bromo-uranium collodion is not employed.

These claims are startling enough, and, by way of verification, two ten by eight specimens are enclosed, the portrait, it is stated, having been taken with an exposure of ten seconds in the studio, and the landscape in seven

seconds. The quality of each is beyond a question very admirable indeed. At once brilliant and soft, delicate and forcible, with a degree of gradation, there is no trace of feebleness, flatness, fog, or lack of force, on the one hand, nor of hardness, crudeness, or lack of the finest gradation or half-tone. We should have judged the prints to have been produced from very perfect wet collodion negatives. The originator, finding Japan too narrow a field for such a process, is anxious to sell it in Europe. And—here is something which seems like a joke, but is manifestly serious and earnest—if any one is disposed to enter into negotiations, and will go to Japan to see Herr Hammenstede, that gentleman will undertake to indemnify him for the cost of the journey out and home again if the experiments do not correspond with the programme from which we have quoted! Those of our readers who desire a trip to Japan can scarcely hesitate in availing themselves of this rare opportunity!

#### THE VOIGTLANDER MEDALS

THE prospectus relating to these medals has just been issued by the Vienna Photographic Society, which intends to offer three silver medals for competition during the present year, and one gold medal for 1875. Should, however, any discovery, improvement, or scientific research of value be communicated to the Society, or to their organ, the *Photographische Correspondenz*, which may be held worthy of such distinction, other medals of gold, silver, or bronze may be awarded to the author.

The gold medal for 1875 is offered for a trustworthy and sensitive dry plate process. Not less than three negatives measuring 26 by 32 centimetres must be submitted by the competitor, one of a landscape, one of an interior without top-light, and the third one of an architectural subject. Moreover, twelve prepared plates must be forwarded, together with any information of importance, such as the preparation of the collodion, &c.

One silver medal will be given for collodions from nature, taken especially to aid the painter. (Portrait studies are not eligible.) If the studies are from animals they must be not less than cabinet size; others must measure 21 by 26 centimetres. The series must number twelve pictures, and duplicate impressions must be sent, together with one negative.

One silver medal will be given for instantaneous stereoscopic pictures, not less than a dozen in the series; duplicate impressions and one negative must be sent.

The third silver medal will be awarded for a series of sixty lantern slides about the size of stereoscopic pictures. The prices of these slides should be given, and the Society reserves to itself the right of purchasing some of them at the prices named.

For the gold medal, competitors must send in their work not later than 1st of March, 1875, to Dr. E. Hoinig, III Hauptstrasse 9, Vienna, the parcel to bear a device or motto, which is to be repeated with the name of the competitor, contained in a sealed envelope. For the silver medals competitors must send in not later than the end of October of the present year. Competitors must qualify for the competition by becoming members of the Vienna Photographic Society.

#### THE AUSTRIAN ORDNANCE SURVEY.

IN *Meyer's Journal* we read an account of the Austrian Ordnance Survey Office, which employs photography largely in the production of maps and plans. By the aid of the camera the expense attendant on copper-plate engraving and lithography is, to a great extent, dispensed with, the main advantages of photography being rapidity of production, and economy. The original drawing must, in the first place, be executed with more care, it is true, and with greater precision, than in the case where the map is afterwards to be engraved, or lithographed; but, if this operation is a little more time-taking and costly, it

must be remembered that the subsequent processes are much simpler.

If the original drawing from which an engraving is to be made is estimated at one hundred florins, then the graving must be put down at not less than six hundred florins, making seven hundred in all. The drawing for photographing from may be set down at two hundred florins, taking the negative at ten florins (which is an outside sum), and the retouching at thirty or forty (the price of the metal plate is in both cases omitted), and we find that the new process costs but two hundred and fifty florins, against seven hundred on the other hand.

As regards the periods of time necessary in the production of these maps, we may state them as follows:—In engraving, the drawing would take six weeks, the graving six months (rather more than less), making together seven months and a half; in the case of photography, or photo-zincography, rather, the original drawing takes eight weeks, and the photographic retouching takes six weeks, altogether three months and a half. The advantage of employing photography is greater when deep, dark lines have to be produced, for these are very difficult of production by the graver, and take a long time to do; while, on the other hand, it is easier for the draughtsman to produce thick, heavy strokes than fine and delicate shading. The best and finest executed drawing of this kind would only cost hundreds, where the engraving would cost thousands, and it would take but as many months to produce as would be required years in the other case. The best proof of this is afforded by the map of Central Europe, which now consists of more than two hundred sheets, and which has been zincographed at the Survey Office, at Vienna, on a scale of 1:300,000. Thirty-five draughtsmen have been engaged for nearly six years in drawing this map, and it is now almost finished, while its reproduction is going on rapidly, so that the giant work is quickly approaching completion. If, however, all the maps had to be engraved upon copper, which would have necessitated the assistance of an army of artists, what an incalculable time would the work have taken, and what a terrible sum it would have cost!

As regards the technical production of these maps, it may be mentioned that all the finer lines, which are exceedingly difficult to mark with the pen, may simply be left out of the drawing, and sketched in afterwards in retouching with the graver. Things which are more easily engraved than drawn, and for which the engraver requires no original to copy from, are also omitted in the drawing, as it is not the intention of the authorities to abandon altogether the other graphical arts, but only to confine them within narrow limits, and, by employing the methods in combination with one another, to produce results of acknowledged excellence with a minimum expenditure of time and money.

#### FRENCH CORRESPONDENCE.

WHILST M. Leon Vidal continues his experiments with the heliochromic process, he has elaborated and is making considerable progress in the matter, as will be apparent at the next meeting of the French Photographic Society. M. Dueos du Haaron is also working to complete a method of heliochromy, the details of which he made known some years ago. The readers of the PHOTOGRAPHIC NEWS will no doubt remember that M. Dueos obtained some coloured pictures by passing the light through glasses differently tinted. To-day we have received from this diligent investigator a little pamphlet, in which he makes known some modifications made by him in the original process. I send you herewith a specimen of his work. The first method consists in producing:—

a. Three negatives in the camera of the same object: the first through the medium of green glass, the second through the medium of blue glass, and the third through orange glass.

b. To obtain by pigment printing, or similar methods, such as chromo-photography, Woodburytype, &c., a red image with the first negative, a yellow image with the second, and a blue image with the third; these three images superposed one above the other constituting together the finished heliochromic image. Among the difficulties which the operator has to encounter is the great duration of the pose necessary to obtain the clichés in the camera through the medium of the orange and green glass, and the extreme intensifying required in these cases. His more recent experiments have served to diminish considerably the exposure of the negative furnished by the red and green light, by employing a collodion which does not differ very much from that generally used, viz., iodised collodion *à la coralline*, and substituting glass for the paper for the clichés he requires.

Experiments made by M. Dueos show that the iodized collodion coloured with coralline is still more sensitive to red light than the bromised coralline collodion referred to by Dr. Vogel. The rapidity of impression is still greater in the case of the green and yellow light. As to the blue light, or violet, this impresses the collodion instantaneously.

These are results which will interest all photographers beyond the connection in which they were obtained, for they will be of veritable importance in the reproduction of paintings, and in more accurately representing all that which contributes to make a harmonious picture, and which is often lost in the photographic copy of a painting.

I have received from a provincial photographer, M. Thierrée, fils, of Bresles, the details of a printing process which is very economical, and which at the same time furnishes very fine prints, the permanence of which the author believes to be guaranteed. The basis of the process is the simultaneous coagulation and sensitizing of the albumen, and to effect this the silver bath is thus compounded, viz.:—

Distilled water	...	...	80 cub. cents.
Crystallized nitrate of silver	...	...	12 grammes
Alcohol at 40° C.	...	...	20 cub. cents.

The paper is floated upon this solution, and allowed to remain in contact with the liquid for three or four minutes. Raising one of the corners with the left hand, and holding in the right a glass rod, the face of the albumenized paper is freed from the excess of liquid by passing it over the rod two or three times. The superfluous solution falls into the bath, and the paper is suspended to dry, an event which soon takes place after the paper has been thus drained, for a quarter of the moisture hanging to the surface consists of alcohol. Among other advantages, the use of a rod has the effect of restoring to the bath an important quantity of solution, and thus maintaining the standard of its volume and quality for a longer period.

The bath is of twelve per cent. strength to begin with, although this is not absolutely necessary, and it is employed until it has fallen to five per cent., after which it is brought back to its primitive strength. It also receives an addition of alcohol from time to time, according as the operator may deem the same necessary, judging from the odour it exhales. In any case, whether the bath is of twelve or five per cent. strength, the pictures have the same intensity, and the same rich tone and brilliancy, provided there is sufficient alcohol, and the amount of the same is greater when the bath is weaker.

M. Thierrée assures me that never, even in very hot weather, does the bath become discoloured, the coagulation of the albumen being complete. There is no need, therefore, to fear the advent of sulphur in the silver bath. The latter may be retained at a very low degree of strength—five or six per cent.—and will still yield prints of an irreproachable character. This minimum of silver is amply sufficient to transform into chloride of silver the salt mixed with the albumen, and to convert a portion of the latter into albumenate of silver. Finally, the paper,

freed from the greater portion of the nitrate which is usually left upon its surface, will keep white for a considerable period. In fact, the albumen, being rapidly coagulated by contact with the sensitizing liquid, becomes less permeable, and protects the body of the paper and the sizing of it.

The economy resulting from this process is considerable. To print five thousand cartes-de-visite, and five hundred prints, whole plate size (taking into account sheets lost, and bad impressions), our correspondent employed two hundred and seventy-six whole sheets of paper, and used but two hundred and eighty-nine grammes of nitrate of silver, being at the rate of 1.05 gramme per sheet. If he had employed instead a bath of fifteen per cent. strength, without the aid of a glass rod to drain the sheets, he would have been compelled to maintain it at a strength of twelve or thirteen per cent., and the proportion of silver absorbed by each sheet would have amounted to about three grammes. As much, therefore, as eight hundred and twenty-eight grammes would have been necessary of nitrate in this case, instead of two hundred and eighty-nine. This proves that, with the addition of alcohol, we may allow the strength of the bath to fall very considerably without inconvenience; but it must be remembered that, there being less silver in the paper, there will be very much less found in the washings and in the residues.

To resume: the advantages which M. Thierrée claims in favour of his process are the following:—Consolidation of the albumen film, which is the true basis of the image; maintenance of the volume of the bath and its state of purity; rapid desiccation and long preservation of the paper; and economy in the use of silver.

Some attention has lately been given to the action of hydrogen, pure or mixed, upon nitrate of silver. M. Pellet, who has made some experiments upon the same subject, has just communicated the results to the Academy of Sciences in a memoir, of which the following is a brief summary:—

Firstly. A solution of neutral or slightly acid nitrate of silver is not reduced by pure hydrogen in a cold state.

Secondly. Alkaline nitrate of silver undergoes, when cold, an incipient reduction in proportion to its alkalinity, and an elevation of temperature accelerates the reducing action.

Thirdly. Hydrogen is without any action upon a solution of acid nitrate of silver, whether cold or warm.

Fourthly. Nitrite of silver cannot exist in the presence of nitric acid, especially in a warm state.

ERNEST LACAN.

**A TOBACCO PRESERVATIVE FOR DRY PLATES.**  
Mr. W. H. WATSON informs us that he has had considerable success in using tobacco as a preservative. He adds:—

“I have placed the formula in the hands of a friend—an amateur—and he tells me he is going to adopt it in preference to others which he has tried. I subjoin the formula for preservative herewith, which will keep for some time after preparation:—

Tobacco	...	...	...	20 grains
Gum arabic	...	...	...	10 „
Water	...	...	...	1 ounce

Boil the tobacco in the water, which you will find to make a saturated solution, and on cooling to throw down a portion of the soluble matter out of solution. Filter, and in the filtrate dissolve the gum. I have found tobacco *per se* to give good results, but prefer to add the gum when the plates are to be kept for some time.”

#### A NEW PHOTOGRAPHIC PAPER.\*

WHILE in former days excellent paper for photographic purposes was produced by at least seven or eight factories, at the present day we are dependent upon two manu-

facturers alone, for it is well known that Messrs. Steinbach and Co. (of Malmedy) and Blanchet Bros. (of Rives) now supply nearly all the raw paper required by photographers. The last named firm, whose paper is much sought after, but who, of late, have been troubled with defects in sizing, and metallic spots, has recently undertaken the manufacture of a raw paper, which if the price is not too high, should be deemed faultless. To distinguish it from the ordinary Rive paper, which will be manufactured as before, the new paper carries a watermark of three stars, and it will be prepared of similar weight, viz., from sixteen to twenty pounds per ream. The sheets are exceedingly clean, and of a very homogeneous texture. We have desired Dr. Schnauss to submit the material to chemical examination, and the results of his investigation we here annex.

#### EXAMINATION OF THE NEW RAW PAPER OF BLANCHET FRERES ET KLEBER, OF RIVES.

(1). Treated with iodine water, it became uniformly blue, and maintained this colour for a long time, a proof of the absence of  $\text{SO}_2$  and  $\text{S}_2\text{O}_2$  salts (sulphurous and hyposulphurous salts).

(2). *Test for the sizing.*—Treated with ether which had previously been shaken with  $\text{SO}_3$  (sulphuric acid), and then dried, the paper allowed moisture to pass through, a proof of the vegetable character of the sizing (resinous soap).

(3). *Ashes.*—The paper leaves behind a rather large amount of white ash, which has a strong alkaline reaction. Water does not dissolve it to any extent; dilute acid dissolves it partially, with the development of gas. The residue is silicic acid; the muriatic acid solution contains, besides traces of  $\text{Fe}_2\text{O}_3$ , almost nothing but  $\text{CaO}$ , which was found in the ash in the form of sulphate of calcium. Curiously enough, no trace of alumina could be found, although in the sizing of the paper alum is employed.

(4). *Behaviour of the paper as regards the action of the silver upon the sizing.*—This is, of course, the most important point of the investigation, and the sizing must especially be taken into consideration, for the inorganic properties of the paper, as also the pure cellulose, may be considered to be without any action upon the silver solution.

To remove the sizing (resinous soap) the paper was digested for some time in water containing a little  $\text{NaO}$ , and the solution was then filtered and carefully evaporated. A part of the filtrate was accurately neutralised with  $\text{NO}_3$ , and there were separated flakes of resinous acid, and then a few drops of silver solution were added in the dark. A whitish precipitate was at once formed, which soon changed to a yellowish-white. After a few days' preservation in the dark the tint became of a dark flesh colour. The paper itself behaved in the same way in contact with silver solution. It was dipped into silver solution for some minutes, and preserved sheltered from the light, but with access to the air. Very soon it became of a brownish-yellow tint, which gradually darkened. The freshly-silvered paper, exposed to sunlight for a few hours, does not change its white colour, a sign that the browning is due to a decomposition, in a moist atmosphere, taking place between the sizing and the silver solution. As soon as this occurs the silvered paper becomes more sensitive to light. If protected from the access of light, and neither dried by means of hygroscopic bodies nor artificial warmth, the silvered paper keeps for an almost indefinite time undecomposed, as, for instance, in a corked bottle or capsuled vessel. In the same way, also, does the silvered albumenized paper behave if likewise kept from the light.

(5). A muriatic acid digest of the unburnt paper was also carefully examined by way of control experiment, and again traces of  $\text{SO}_3$ ,  $\text{Fe}_2\text{O}_3$ , and much  $\text{CaO}$  was found, but no alumina; the sulphuric acid and iron were due, probably, to the bleaching agent employed, and the iron rollers used in the manufacture. Metallic iron particles, which cause metallic spots, were not present.

## ON THE APPLICATION OF THE POWDER PROCESS IN PHOTOGRAPHY.

BY J. B. OBERNETTER \*

So far as I am aware, Mr. J. Wyard, of London,† was the first who, in 1860, made use of the powder process to produce pictures upon enamel, and burnt them in upon glass and English porcelain. Joubert, Lafon de Camarsac, and Poitevin all worked in a similar direction. In the London International Exhibition of 1862 Lafon de Camarsac exhibited several enamel brooches, as also a porcelain cup upon which photographs had been burnt. The novelty of these objects impelled me to make some experiments in the matter, and these at once convinced me that the subject was one which would repay investigation.

From the year 1862 down to the present moment I have occupied myself with the powder process, and, as is well known, have practised it with some success. The fact that my communication on the subject of reproducing negatives has met with approval has induced me to publish in the *Photographische Correspondenz* the details of my researches in this direction. I trust that the high degree of success which has attended my efforts may move others to adopt the process, and further contribute to its value.

In the early days very little was known of the various methods experimented with, and it was only by private correspondence that I was enabled to obtain any information respecting the work of the gentlemen above named. I continued my experiments systematically, and within a year I had elaborated a method which worked in a most perfect and trustworthy manner. Many processes have been published from time to time, up to the present day, of the modes of producing enamel photographs. If we look closely into these methods we find scarcely any difference among them, but there are the same defects in all of them, rendering sure and certain success impossible; these defects have been carried down to the present day, and appear in the most recent processes published.

Till now it has been the custom to prepare a mixture of bichromate salts and some organic body, such as albumen, gum, dextrine, gelatine, sugar, &c., and to pour a thin solution of this solution upon glass, paper, or porcelain; the film was rendered partly insoluble by exposure under a positive picture, and dusted over with fine enamel powder, which adhered only to those portions of the surface where the light has not impinged upon it, and this dusting of the image, so to speak, develops the picture. Whether the picture was transferred by means of collodion, or whether it remained upon its original basis, it was invariably washed with acid to free it from the superfluous bichromate contained in it. The employment of an acid to get rid of the chromium salt is, however, the sole reason why all hitherto published methods have given unsatisfactory results, for under these circumstances the enamel pigments employed never possess an agreeable tone, and do not attain a brilliant gloss when burnt in upon the porcelain. My first experiment showed me that the cause of matt discoloured pictures was due to a chemical change which the pigments employed had undergone. The composition of the enamel employed is well known, and I submitted a sample of it to the action of the agents employed in the process, and then prepared a picture with the powder for comparison with another image burnt in with enamel pigment which had not been acted upon. The result of my experiment was as follows:—

Water and organic bodies, such as gum, albumen, &c., are without any action. Enamel pigment treated with these, and then washed, come out of the furnace like normal colours. The chromic salts destroy the lead in the colours forming chromate of lead. If the colour is treated with an excess of a solution of bichromate, the whole of the lead compound in the pigment is decomposed, and, instead of the original important flux, the enamel contains

chromate of lead. This latter, when burnt in, possesses no gloss; but if, to such a pigment containing chromic acid, some fresh flux is added, then the former recovers its original tone and brilliancy. This result is obtained when the action of the chromic acid has been but very brief, and the chrome salt is not a simple chromate, but rather an alkaline salt. The change of colour may therefore be avoided by the addition of more flux, thus preventing the action of an acid chromate salt upon the pigment. If the enamel pigment is treated with any acid, then the whole of the flux is decomposed, the metallic oxides, which form the colouring matter, being partially dissolved and changed; the colour loses its tone and brilliancy, and it is no longer an enamel pigment, but a mixture of difficultly soluble metallic oxides, such, for instance, as the oxides of copper, cobalt, &c.

In all processes hitherto published it is recommended to immerse the powder image in dilute acid, or to wash it with the same, so that the excess of bichromate salt may be dissolved away, and the obnoxious compound and tint in this way removed; but, as I have already shown, the dullness of the image and the bad colour of the burnt-in image are to be ascribed solely to the action of the acid upon the picture.

The remedy is obvious: if, instead of an acid, we have recourse to an alkali solution, this neutralises, on washing, the bichromate salt, and acts as a solvent upon any chromate of lead that may have been formed; at the same time it does not attack either the metallic oxides or the flux. Enamel pigments do not suffer any change on being exposed to the action of dilute alkali, or soda solution. These simple experiments I made ten years ago, and they were the cause of my success in working the process. Those who have experimented with the method, and have abandoned it from vexation due to their ill-success, should try once more, and, instead of an acid, employ potash or soda solution for washing. The result will be sure to repay one.

All published methods are at once practical if only the word acid is struck out. I am firmly convinced that all those who at the Vienna Exhibition exhibited such beautiful enamel photographs employed an alkaline for washing out the chromium salts. And if I cannot prove that I am the first, directly or indirectly, to discover this matter, I will, at any rate, be the first to publish it for the good of all.

It is unnecessary for me to speak of the proportions of the sensitive solution. Gum, dextrine, albumen, or gelatine, combined with more or less sugar, to which eight or ten per cent. of bichromate of ammonia are added, and water in sufficient quantity, always give results of some kind. I employ the simplest and the most uniform kind of preparation for porcelain pictures, viz., gum or grape sugar, and by adding glycerine, correct the solution according to the degree of moisture in the air at the time being. This latter operation is the most difficult of all. Only practice and experience can here indicate the proper course to pursue.

Many take the trouble to prepare the solutions in the dark, and to coat their plates in the dark, and apply the powder in the dark also. Irrespective of the fact that a solution in light does not lose its good qualities, the dry plate, it may be stated, does not suffer by being exposed for a short time, such as suffices for the placing of the film in the printing frame and applying the powder to the action of daylight. All my porcelain and glass pictures are produced in the ordinary working room of my studio. These remarks on the production of photo-enamels are, of course, only supplementary to the details of processes already known and practised.

Those who have worked the powder process will have become aware of many possible applications of it. At the time I was producing my porcelain pictures they were making in Paris the beautiful glass stereoscopic slides. Pictures of this kind I employed as positives for the

\* Read before the Vienna Photographic Society.

† See remarks on another page.

production of burnt-in photographs upon cups, saucers, &c. These stereoscopic pictures were not varnished, and were, for the most part, upon very thin glass, and easily injured. My plan of proceeding was to prepare a sensitive solution of—

Gelatine ... ..	1 gramme
Gum ... ..	2 grammes
Sugar ... ..	8 „
Bichromate of ammonia ... ..	4 „
Water ... ..	150 „

and with this a glass plate was coated. The film, when dry, was exposed under one of these stereoscopic slides, and then finely divided silver was dusted on, the powder being produced by precipitating a dilute solution of nitrate of silver with acid sulphate of iron solution. The more dilute the solution the finer is the precipitate formed; but washing the precipitate, filtering, and drying it, is a tedious and costly operation. I therefore sought for some other finely divided and innocuous matter, experimenting with oxides of iron, clays, &c., until at last, in graphite, I found a body which seemed to answer every necessary condition, and which, moreover, was not a costly commodity. When I had secured a picture of sufficient vigour upon the plate, I washed it by simply pouring over it a mixture of nitric acid, alcohol, and water, in equal parts, thus eliminating the sugar and the chromium salt. In this way I prepared several positives upon uniformly thick glass, cut them accurately with a diamond to the proper dimensions, and was able in this way to print six or more pictures upon porcelain plates. These positives were all reversed, and yielded, therefore, upon porcelain prints in their proper sense. It would have been just as easy for me at that time to have reproduced negatives, but as such work was not then necessary in my business, and no demand existed for reproduced negatives, I paid no attention to the subject.

Another very interesting experiment is the following. A copper, zinc, or glass plate is coated with a syrupy solution made up of—

Gelatine ... ..	10 grammes
Glycerine ... ..	2 „
Bichromate of ammonia ... ..	4 „
Water ... ..	50 „

When this has dried upon the surface of the metal or glass, it is put under a reversed negative and exposed to light. After printing it is sprinkled with fine zinc powder, and if the plate is desired perfectly flat, one pauses in the operation as soon as the picture appears as a positive by reflected light. If, however, a deeper typographical image is desired, then the plate is breathed upon and dusted so long with zinc powder until the latter has penetrated deeply the unexposed portions of the plate. When glass plates are being used, the operation may be viewed and controlled by transmitted light, but with copper plates the depth of the engraving can only be estimated with the eye as nearly as possible. When the plate is sufficiently powdered, it is washed with water to get rid of a portion of the chromium salt until the rinsing water runs off of a lemon colour, and then the plate is allowed to dry spontaneously. The not quite wholly removed chromium salt suffices to render the whole of the gelatine surface insoluble by long exposure of the plate to light, or by heating to about 150° Centigrade. When, by one operation or the other, the film has been made insoluble, then the surface of the plate is etched by means of dilute muriatic acid. The zinc is dissolved, and the hydrogen formed combines in *statu nascenti* with the insoluble gelatine in contact with it, and renders the latter again soluble.

By moistening with water, the image may be printed from in the same way as a lithographic stone. If a relief is desired, then the whole plate is washed with hot water; as deep as the zinc has penetrated by powdering, so deeply is the gelatine dissolved, and the relief produced. Unfortunately, the half-tones are also deep in this case, and therefore the method is only applicable for reproductions

of line drawings, but these are copied with a sharpness unknown in other processes.

I believe it to be possible to prepare printer's blocks in this way for the printing press. My first pictures in the printing press were thus produced, and in larger editions from one plate I even now have recourse to this method, especially when the subjects present sharp outlines, such as maps, plans, &c.

Unfortunately, I must warn photographers of taking up this class of work, for the zinc powder with which one has to operate is very injurious to health when breathed into the lungs. Half a day's work with the powder produces a metallic taste in the mouth, loss of appetite, &c. It is possible partially to guard against breathing in the dust, but everything that keeps off the dust also prevents one from breathing upon the plates, which is indispensable in working the process. Nevertheless, two or three plates may be prepared daily without personal injury.

These are my most interesting experiences of the employment of the powder process with bichromate salts. In my next communication I will treat of the powder process with iron and other metallic oxides as the sensitive bodies. As in these bodies a suboxide is formed on reduction of the oxide by the action of light, and the former is more hygroscopic than the latter, the contrary result is produced as when the bichromate salts are employed in copying a negative, for in the former case a positive picture of similar beauty is obtained.

## Correspondence.

### IMPEDIMENTA OF THE MAGIC LANTERN.

DEAR SIR,—Allow me to express my surprise and regret that a critical remark made by me in my article upon the "Impedimenta of the Magic Lantern," although just, has unintentionally caused Mr. Nicol to feel so sore. I believe I have had as much practical experience as falls to the lot of many, still I have no ambition to be styled a mechanic, therefore the declamatory effusion of Mr. Nicol does not affect me, as he does not defend his project; and as it has no doubt been smartly criticised by the clique, I will, in Scotch parlance, let that flea stick by the wa'. In Scotland, the old sugar-loaf form of weight may be still used, and I should have thought a quarter of a century's experience would have taught Mr. Nicol that if placed upon their sides, provided that the ledge of the pressure boards is properly constructed, they would lay perfectly safe, without the necessity of depriving him of all the gentlemanly appurtenances he possessed. In this part of the country, the block weight, having a bar handle, and the number of pounds it represents cast in figures upon its top, has quite superseded all other varieties, and Mr. Nicol, I am sure, would allow them to be the very thing required, and that there is no necessity for the iron bars he proposes, which, although they, upon occasion, prove excellent substitutes for kitchen poker or life preservers, would, I should imagine, prove dangerous, troublesome, and noisy cab companions.

I still hold to my opinion that the pressure boards constitute the chief impedimenta of the dissolving view apparatus. I am not aware of the size of that used by Mr. Nicol, but will describe my own. It consists of a pair of lanterns having four-inch condensers, with lamps, jets, tubing, and to light either with gas or oil as may be required. I carry about six dozen slides. All the above are contained in two boxes, measuring about 24 by 16 by 16 inches. My pressure boards, which are boxes, and carry the bags, are 43 by 32 by 6 inches, and weigh about fifty-six pounds each.

After giving these data, I need not point out to your readers the error under which Mr. Nicol labours when he asks what good it would be to do away with the latter unwieldy objects, and substitute in their place a pair of bags which, by a little alteration in the size of the above named boxes, could be packed in them, and conveniently carried either behind or on the top of a cab or by rail. That this is not a Utopian idea I think I can show. I will not dispute the universal ingenuity of Mr. A., but allow him to be capable of anything, from picking a lock—a dangerous accomplishment, by the bye—to taking an observation of the motions of the planets; but it is frequently the case that amateurs allow their imagination to outstrip their judgment, work without

a plan, and throw all caution aside. That this was the case with Mr. A.—and I should not think that he would thank Mr. Nicol for exposing it—is evident, otherwise he would have proved the success of his experiment by inflating his bags with common air, and noticing their action before venturing to use them at an exhibition. Had so clever a man as Mr. A. used his reasoning faculties, they would have told him that the resistance of any machine must be fully equal to any pressure to which it may have to submit, whether from within or without.

Mr. Nicol, being a Ph.D., will no doubt understand that if the heavy head of a man, together with the bones, shoulders, and arms, were unsupported by the spinal column, but allowed to press upon the lungs, unprotected by the ribs, the effect would be fatal, and somewhat similar to what happened to Mr. A.'s bags. In my hasty sketch, necessarily short, I reckoned on the good sense of your readers, and did not name them; but in all instruments of this kind they are a matter of necessity. As an example, I refer Mr. Nicol to the common kitchen bellows, which, if he requires ocular demonstration, he can cut open, and he will find that the ribs prevent their flexible parts being blown out like a bladder.

I cannot claim the idea of forming square gas bags to be used without pressure-boards as my own. They have for a long time been supplied by makers of emulsion, and found to answer well. My proposition was only to remedy some of their inconveniences, and improve their appearance. I believe I may presume, without arrogance, to caution Mr. Nicol not to be too hasty in pointing a moral, otherwise he may, perchance, adorn a tale unconvincible.

While writing on this subject, I wish kindly to suggest to "Oxygen" that in his proposition to use water as a weight he has not taken into consideration that a pint of water weighs only one pound, and thus it would require fourteen gallons to equal 112 pounds, the weight required; bags made of sufficient size to hold such a quantity would be very costly and unwieldy; that the weight upon a pressure-board requires to be placed at that point where its pressure may have a tendency downwards and towards the top, otherwise the gas would not flow, and the bag might be burst; also, that water finds its own level: so that if an open tin case containing the proper quantity could be placed in a right position upon a full bag, the descent of the pressure-board caused by the emission of the gas would so alter matters that the water would be spilt, and, in all probability, the whole affair topple over on the floor.—I am, dear sir, yours truly.

5, Clarence Place, Ifracombe, April 28th. J. MARTIN.

### Talk in the Studio.

**THE PHOTOGRAPHERS' BENEVOLENT SOCIETY.**—The Society has just issued a circular setting forth the advantages to be gained by joining. Photographic assistants would do well to give the subject their earnest attention. A copy of the circular may be obtained of the secretary, Mr. W. T. Wilkinson, 174, Fleet Street, E.C.

**CLEANING VARNISHED NEGATIVES.**—Mr. C. A. Palmer, writing to the *Philadelphia Photographer*, says:—"I have seen many ways of cleaning off varnished negatives, but of course like my way best, and as I have never found any one using it, except where I have taught them, I will give it for the benefit of all. I proceed as follows: I take my varnished negative and pour on it a little concentrated ammonia, rubbing it well over the surface; then setting it in a level place, pour a little more on the centre of the plate, and prepare another the same way; then lay the varnished sides together, and serve another the same way, and continue doing so till I have a dozen or two in the pile. Then set a weight on top and let them lay an hour or so, when the film will easily come off, and, after thorough rinsing, be ready for albuminizing. I cleaned and albuminized fifty quarter-glasses in a little over an hour a short time since. It is much the quickest, and I think the cleanest, method I have ever seen published."

### To Correspondents.

**DARTMOOR.**—A metal box for storing dry plates is in many respects best, but care is required not to leave on the plate any of the metallic particles rubbed from the groove by the edges of the glass. At one time a strong objection existed against wooden boxes for storing dry plates, especially if the wood were pine, as an impression prevailed to the effect that the resinous exhalations produced fog.

**ENAMELLIST.**—The question depends entirely upon the terms of the bargain. Of course, if you purchase a formula as a secret, it derives a portion of its commercial value from the fact that it is known only to a limited number, and such competition as it might aid is circumscribed. You are unquestionably to some extent damaged by the open publication, but unless some guarantee as to communication to a limited number only were entered into at the time you purchased, it does not seem that you have any remedy. Various patents for enamel processes have been taken, but there is none, we believe, in relation to the powder process now in force. Joubert's patent was taken in January, 1860, and is now expired. Some years ago another powder process was patented in this country, known as Leth's process, but we believe it was not kept up beyond the first three years.

**FERRI SULPH.**—We are not quite sure as to what you mean by the "receipt for a good enamel varnish for cartes." The enamel surface which is sometimes applied to cards is not a varnish at all, but a coating of gelatine and collodion, applied in the way we have often described. You will find it described in our last *YEAR-BOOK* on page 117. 2. The production of Rembrandt effects depends upon the lighting of the sitter. We have described the mode of proceeding repeatedly, and it would be impossible to repeat details in this column. All the light is covered up except a small space, near to which the sitter is placed; and reflected lights are secured by the aid of suitable screens. 3. It scarcely seems to us that the publication of births, deaths, and marriages amongst photographers would be of sufficient interest.

**TWELVE MONTHS.**—We should think that your first year's experience ought to be very encouraging, and we should recommend you to persevere, resolving to increase your business steadily. There appears to be every prospect of success. The saleable value of a business depends upon so many things that we cannot very well give even a rough estimate of the worth of yours.

**SIMPLEX VERITAS.**—Our answer was intended to imply that we had always believed that the method employed at Liverpool was one of several known methods, and that similar things had been done some time before. 2. Regarding the preservation of photographs by hermetically sealing them from atmospheric influences, it is probable that in many cases rapid fading would be avoided; but we believe that more photographs perish from the consequences of imperfect fixation than atmospheric influences. If a print be perfectly fixed and washed, it is probable that perfect protection from the atmosphere would preserve it from fading. There is not, and cannot be, any specific time laid down for the fixation of prints. The thickness and character of the paper, the amount of unchanged chloride of silver it contains, as well as the strength and temperature of the solution, materially modify the time. Sometimes five minutes may be sufficient, but, as a rule, from ten to fifteen minutes in summer, and from fifteen to twenty minutes in winter, have been found in practice to answer best for general use. Too long immersion is always undesirable. Our experience leaves no doubt whatever as to the improbability of photographers paying for the hint in question, and of course we have no hesitation in stating our conviction when we are asked. We shall have pleasure in publishing the details. We will return the cutting.

**G. F. L.** suggests that in printing life-size heads, whether from direct negatives or enlarged negatives, rough drawing paper should be employed instead of albumenized paper, the texture of the former being much more effective, he thinks. The suggestion has been made before, and is well worthy of attention.

**M. R.**—The poverty of tone of which you complain is more due to the imperfection of the negative than the toning bath. Your negative is apparently flat and weak, and without a good, vigorous image is obtained in the printing frame from a good negative, you cannot hope for a fine, rich tone in the gold bath.

**F. E.** writes to express regret at the turn of affairs in the Photographic Society, and to express his approval of our comments last week. He asks if it be absolutely certain that those identified with the origin of the agitation were again summoned to be ready for combined action? as, if this were really so, it was, he thinks, "a menace which in itself showed that the reconciliation was hollow, that it was, in fact, but an armed truce, and showed that the demon of distrust was still in the ascendant." If that were not so, "if no preparation of the kind, for opposition, existed, he thinks it was very unwise on the part of Mr. Glaisher not to make clear, in a conciliatory spirit, the difficulties in which the council were placed, as it would have been easy to show an impartial audience that reconciliation necessarily meant a restoration of the state of things before the quarrel." In any case, he adds, "an attempt to enforce conditions as a basis of reconciliation simply amounted to coercion, which it must have been clear to any one could not be acceded to." Finally, he asks: "Is every avenue of harmonious co-operation closed, or are there still means of securing agreement?" Candidly, we fear not. The best thing that can now be done, so far as we can see, will be to get a new code of rules out and a new general election by the entire suffrages of the society. We fear that further discussion of the question will now avail little, and we have therefore only given the chief points of our correspondents' long letter.

Several Correspondents in our next.

## The Photographic News, May 8, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY ON THE STAGE—PHOTOGRAPHIC ILLUSTRATIONS—THE OBERNETTER REPRODUCTION PROCESS—THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

*Photographers on the Stage.*—Everybody expects to be parodied now-a-days, and the photographer is not likely to be exempted. It is surprising, indeed, that more advantage is not taken by our play-wrights and farce-writers of the incidents of a photographer's life, for many of them are especially calculated to promote, or mystify, the plot of a play. As we pointed out a little while ago, the few times in which photography has been seriously employed upon the stage to supply some proof, or afford necessary evidence, in bringing about the *dénouement*, as in the case of the *Octoroon*, and other pieces, so much ignorance is generally displayed upon the part of the authors, that in the eyes of a photographer the result is ludicrous in the extreme. The business between a photographer and his sitters, which one might imagine would form a capital basis for a humorous bit of acting, has only—in our experience, at any rate—been attempted once in this country, although we remember a very funny lecture given at the Crystal Palace by our famous comedian, Mr. Toole, who used to boast (not without some truth) that his glass-house was the biggest in the world; that his portraits were so large that instead of *plates* he had to use *dishes* for them; and that, although it was a difficult thing in photography to make a bath and "set a plate," you need not "sit up late" to do it. Mr. Toole always succeeds, whether he wants his audience to laugh or cry; but he is never more mirth-moving than when, with mock gravity, he takes to lecturing on chemical subjects, and expounds the vegetable nature of amber, which, he says, is not to be confounded with the Epsom salts of commerce, that is grown like mustard and cress upon a blacking bottle, and sold to the public as cyanide of potassium. The single instance we know of, of a farce having been made from the materials of a photographer's studio, was one written by the late John Brough, one of the most genial spirits that ever breathed, who, it will be remembered, made a reputation in science as editor of the *Laboratory*, and author of "Fairy Tales of Science," and was one, also, of the Brothers Brough, whose bright extravaganzas, in the days of Vestris and Robson, are not yet forgotten. There were only two actors in the farce, if we recollect rightly, and these assumed, one after the other, various guises, and represented oddities who came to sit for their portraits, and worry the poor photographer. The author created one rôle, and the present survivor of the four brothers, Lionel Brough, whose genuine humour every playgoer of to-day is familiar with, supported the other, so that the fun and merriment of the piece were fully developed. It was produced at the time when the song of "Old Dog Tray" was the rage, and those who remember something of the words of that popular ditty will see how well the sound of several phrases is imitated in the photographer's song, who, in introducing his sitters, sings:—

"From this heterogeneous crew I've picked out one or two,  
Who represent the nation, that we speak of every day.  
And these will clearly show that wherever we may go,  
We find subjects plenty to *pour-tray*.  
For old or grey, we're ever grateful,  
And object not to sitters young and gay,  
But we only show to you the portraits of a few  
Whose photographs are more *outré*."

*Photographic Illustrations.*—It is encouraging to see how surely, if a little tardily, photography is making its way as a means of illustrating contemporary literature. It is no novelty, of course, to see a book illustrated by photography, but those hitherto produced have, for the

most part, enjoyed but limited circulation, being put forward by their publishers more as tentative essays and experiments, rather than as commercial speculations to realise a profit. It is only during the last year or two that booksellers have seen their way to employing photography in competition with engraving, and an excellent example of what the art can do is afforded by the Princess Lichtenstein's work on Holland House, which is profusely illustrated by Woodburytypes. Another step is now being made, and we are right glad to find that a journal with so large a circulation as the *London Figaro* is giving its readers a photographic illustration every week, the price of the journal, together with the frontispiece, being but twopence. The first picture issued is a carte portrait of Madame Nilsson, by Pierre Petit, of Paris, which has been printed, we should think, by Messrs. Goupil, of Asnières, by the Woodbury, or as they term it, photoglyptique method. The carte is a charming production, and as well printed as a first-class silver picture, to which, on the score of permanence, it is of course vastly superior. Mounted on a card, its ordinary price would be a shilling, and yet the purchaser is asked but a fraction of twopence for it. The cost of production of these pictures, when an edition of forty or fifty thousand is required, is no doubt comparatively small, for in this case we must suppose that a margin for profit remains to the publisher. The appearance of a newspaper with a photographic illustration must be regarded, therefore, as a grand stride in commercial photography, proving as it does, the possibility of producing pictures of such excellence at so low a figure. By Lichtdruck, or Heliotype, photographs could doubtless also be obtained quite as economically; but even if possessed of the same delicacy and detail, they would scarcely be so brilliant, or approach so nearly a vigorous silver print, such as Madame Nilsson's portrait appears to be. In Paris an attempt was made a year ago to illustrate a theatrical journal in the same way as is now being carried out here; but although the enterprise continued for some time, and is, for aught we know, still being carried out, the circulation of the journal was not such as to command a great success. One grave drawback was the unsuitable mount presented by the thin, flimsy newspaper, which detracted very much from the finish of the photograph; and we are glad to see a solution to this difficulty is pointed out by the editor of the *Figaro*, who recommends those desirous of preserving the picture to remove it from the paper by moistening the back with a wet sponge, and to transfer the image to a suitable album. Hot water should never be employed for unmounting a Woodbury print, as there is always a risk of disintegrating the pigmented surface.

*The Obernetter Reproduction Process.*—Some experiments made with the Obernetter method of reproducing negatives induce us to think very highly of this plan of multiplying clichés. Very much depends upon the fine quality of graphite that is used, and a sample specially ground for us by Mr. Newman, of Soho Square, answered the purpose admirably. As the most delicate half tones in the photograph are made up simply by particles of graphite adhering in greater or less quantity to the hygroscopic image, it stands to reason that, unless the material is an impalpable powder, pinholes or specks innumerable will be seen throughout the picture. Obernetter recommends the pouring off of the superfluous sensitive mixture as soon as the plate has been coated with it; but this it is difficult to do sometimes, for, on tilting the plate, the liquid is apt to run off like oil, and leave bare glass in places. By allowing the liquid to remain upon the plate for a minute or two, before tilting off the superfluous part of it, there is no risk of this *contretemps* happening. A very little practice is necessary to obtain a result, although to become perfect and certain in the manipulations naturally requires care and attention. Prints from our own first results were full of detail, but a little flat, but this was simply owing to being too sparing in the application of the graphite. Of two

negatives which M. Obernetter has been good enough to multiply for us, the originals are in no way superior to the reproductions, for impressions from the original and duplicate are almost, if not quite, indistinguishable.

*The Photographers' Benevolent Association.*—The English Photographers' Benevolent Association does not seem to float so readily as the sister society in Paris. The number of members in the Paris association already amounts to hundreds, and the directors are enabled, therefore, to do something for photographers and photographers' assistants beyond providing for them in old age and sickness. A registry is kept of all those requiring places, or desirous to effect an exchange, or of bettering themselves, and this registry is consulted by those in Paris or in the provinces who are looking for assistants in the various branches of the art. Indeed, the French association has a *locale* of its own, and fulfils the office of club as well as that of a benefit institution. It would be well, therefore, when our own association gets into working order—and the day, we hope, is not far distant—to study the regulations and working of the Paris institution, so that we may ascertain whether anything is to be gained by appropriating some of the arrangements therein adopted. Until, however, subscribers come forward more numerously to support the association—even if it is only to give it a fair chance at starting—it would not be wise of the authorities to adopt a wider programme than that now put forward, which seems to have been drawn up with much care and attention. Once more we earnestly advise all those who look to photography for a livelihood to consider the prospectus just put forward by the association, with a view to giving it a hearty and cordial support.

### SPECTRUM ANALYSIS AND PHOTOGRAPHY.

BY J. NORMAN LOCKYER, F.R.S.\*

So much for the application of photography to what may be called the celestial side of spectroscopy; but let me tell you that this, so far as spectroscopy is concerned, does not exist. To the spectroscopist all nature is one, and it is absolutely impossible to make a single observation, either on a sun, or a star, or a comet, without bringing chemical and physical considerations into play; and I pity chemists if they employ the spectroscopist in terrestrial chemistry—they have not done much in that way yet—but I pity them if they commence operations in that way, unless they take the sun and all the various stars of heaven into their counsel when they do it, because the spectroscopist is absolutely regardless of space, and shows us that the elements which are most familiar to us here, or at all events a good many of them, are present in the most distant stars, and the spectroscopist shows us those elements existing under conditions which are absolutely impossible here. Therefore, if a man is studying cadmium chemically, and does not go to the sun, and see what cadmium is there, he simply leaves half his evidence out of the record.

There is another point, too: spectroscopy is, above all things, molecular. We are dealing with the ultimate atoms, or molecules, or whatever you like to call them, when by means of the short wave temperature of the spark we drive a substance into vapour. And if chemists, for instance, will simply ask themselves which substances have their lines reversed in the solar spectrum, I think before they have thought that problem out—that very simple problem, as it seems—there will be such a flood of light thrown upon terrestrial chemistry, that the only wonder will be that it has not been seen before, years and years ago. These, you will say, are theoretical applications. It is perfectly true; and there are a great many other theoretical applications that it would be my duty, as it would be my pleasure, to bring before you, if time permitted. But that is not all. I have to refer to the application of the spectroscopist in what are considered by some people more practical directions, although I am always sorry to see science get down to its practical side, because, when it has got there, it is more or less used up. The more you deal with the most abstruse considerations of science, the more likely you are to get practical applications out of them, if you care more for practical applications than for abstract truths. But, however, in my next lecture I shall have to

talk about the practical applications, which some people may consider of more importance; but before I do that, there is one more method that I wish to call your attention to. You have already seen how excessively important it was to use a slit instead of a round hole in these experiments. It was the verdict of Wollaston, and it was the verdict of Becquerel and Draper, as I have shown you to-night with regard to photography. You have also seen that we can use the circular corona as a slit equally well. Therefore, if we like to take a long slit and divide it into as many portions as you choose, we see at once the improvement that we introduce into photography. All we have to do is to divide that slit into portions, as it were, by letting a window run down the slit, and when the window has arrived at the second part of the slit, let in light from a new source. Let me show you some photographs which illustrate better what I mean. Here is a single photographic plate on which a new method has enabled us to register no less than four different spectra. Those of you who are more familiar with photographic processes will immediately see how it is that the number has not been forty instead of four. Having a slit of a certain length, if I open all the length of that slit at once I should get a spectrum the breadth of which would depend upon the length of the slit; but if I commence operations by allowing the light first to come through one small portion of the slit, then we shall get the light from the particular metal which I employ in the electric arc falling on one part of the plate, and registering itself on the photographic plate. Then, if I close up that part of the slit, and open another one, I shall be able, through that newly opened part of the slit—all the rest being closed—to photograph on the plate the spectrum of another substance, say iron. Then, having used up that part of the plate, I can close that portion of the slit, I can bring my window lower down, and there we have the spectrum of cobalt. The window has been brought further down, and there we have the spectrum of nickel, so that we have, as the work of some eight or nine minutes at the outside, a photograph—not a perfect one in this case, but this was the first one taken on this method—which will register with the most absolute and complete accuracy and certainty not less than 1,000 lines. Now, a careful student of these lines, working as hard as he can, thinks himself very fortunate if he can lay down ten an hour. Therefore, as ten an hour are to 1,000 in seven minutes, so is the eye to photography in these matters.

I have another photograph of a somewhat similar nature, which I am anxious to place before you. We have here an absolute comparison rendered possible, by means of photography, between the lines of the spectrum of iron and the lines of the spectrum of the sun. You see that in the case of most of the thick lines you get a line in the solar spectrum corresponding with the lines of the iron. And, more than this, you see, I hope all of you, that these lines of iron are of different lengths. The reason of that is that I have been careful to photograph on the plate the lines due to the various strata of iron vapour, from the rarest vapour, which is obtained at the outside of the electric arc, to the densest, which occupies the centre of the core, and you will see the most beautiful gradation as we pass from the outside part of the spectrum to the inside. This inside part represents the complete spectrum of the core, and the outside the incomplete and almost mono-chromatic spectrum of the vapour which surrounds the denser core in the middle of the spark; thus we have practically reduced the spectrum of iron to one line instead of 460. That is the first photograph of the kind that has been taken; I say that, not because I am proud of it, but because you all know how enormously photographic processes are likely to be developed, the moment not one individual, but a great many try their hands upon them, so that an enormous improvement upon what you now see may be anticipated. Not only have we developed, in the application of photography to spectroscopy, a valuable ally to science, as we have in the application of photography to astronomy—and you know what that has done, and what it is going to do—but we have, I believe, what we may almost call a new chemistry, some day to be revealed to us by means of photographic records of the behaviour of molecules. Recollect that the difference between the iron spectrum of one line and the iron spectrum of between 400 and 500 lines is simply due to the difference in the arrangements of the molecules or atoms of iron in the centre of the electric arc and its exterior. There is one question which all lovers of the spectroscopist may ask of photographers, and that is this: why should we any longer be confined in registering spectra to the more refrangible end of the spectrum, when one of the very first spectra of the sun that was ever taken was a complete photograph of the spectrum, including

\* Concluded from page 208.

not only the blue, the green, and the yellow, but the red, and the extreme red? I think that if photographers will study the action of light on molecules, and read that extraordinary paper of Becquerel's, and will give those who are familiar with the spectroscope, and those who are anxious to promote the progress of spectroscopic research, a means of extending photographic registration, not only into the green part of the spectrum, which they do already with difficulty, but to the extreme red, then the use of the eye will almost entirely be abolished in these inquiries. And although no one has a higher estimate than myself of the extreme importance of the eye, I think that the more it is replaced by permanent natural records in these inquiries, the better it will be for the progress of science.

### A NEW SYSTEM OF ENGRAVING PLATES FOR PHOTOGRAPHIC PRESSES.

BY J. LUTHER RINGWALT.\*

It has become a popular entertainment in some theatres and lycceum halls for artists to draw caricatures, scenes, or portraits in the presence of an audience. I propose this evening to attempt the more difficult task of having drawn and engraved in your presence a plate from which impressions can be printed, and to explain the system by which such a feat is rendered possible. The preliminary preparations consist in the coating of a zinc plate with an acid-resisting varnish, and the subsequent scoring of the coated plate with parallel incisions, so that the effect of a series of straight alternate white and black lines is produced.

The art of engraving on wood is older than the art of printing with moveable types, inasmuch as block books, cut on wood, preceded the products of Guttenburg and Fust; and it is a somewhat remarkable fact that while wood engraving received an impetus from the invention of printing, which led to its rapid development to a very advanced stage, it gradually became, from a period near the commencement of the seventeenth century to a time near the close of the eighteenth century, so much neglected and abandoned that it fell almost wholly into disuse. The works requiring illustration during this period were embellished almost exclusively by the products of the copper-plate press. In the latter portion of the eighteenth century, however, a revival of wood engraving began. The famous Bewick was the pioneer in this movement, and he restored the art to such a high state of perfection that he had numerous successors, whose labours became better and better appreciated, and evoked a larger and larger demand as the fact became apparent that, by a proper degree of care and skill, and the employment of good art assistance, pictures capable of being printed on the typographic press could be produced of so fine a grade that, for most practical purposes, they would answer all the ends of copper-plate engraving. Copper or steel-plate pictures remain the most elegant and finished of any of the black products of printing, but they are subject, from an economical standpoint, to a great disadvantage, in the slowness and costliness of the methods by which they are printed; for while the old hand printing press, capable of turning out only a few hundred impressions per hour, has been superseded by an immense variety of machines, some of which can print twenty thousand copies an hour, and while thousands of copies of excellent wood engravings are printed per hour on various wood-cut presses, the copper-plate press is scarcely more rapid in its operation to-day than it was two centuries ago, and this conjunction of circumstances goes far to account for the rapid revival and extension of wood engraving during the last eighty or ninety years, and the relative decadence of copper or steel-plate engraving for popular purposes.

Desirable, however, as the products of wood engraving are, alike on account of their beauty and the rapidity and cheapness with which impressions can be taken, the art of producing them is tedious, difficult, intricate, and expensive, and this fact has led to the employment of no inconsiderable

amount of inventive genius in attempts to discover acceptable and economic substitutes. The motive which led to the discovery and extensive application of lithography was, if not identical with, at least akin to this incentive. The Daguerreotype and photograph had their birth in the same or a similar desire, and the Woodbury process is a still later outgrowth of the modern demand for illustration. Still, neither of these inventions exactly answered the precise object of supplying forms or plates from which pictorial representations could be multiplied with the readiness or rapidity attainable on either of dozens of typographical printing presses, and it is only during a recent period that the prospect seemed hopeful of finding substitutes for wood engraving that were in all respects entirely satisfactory.

One class of the experiments directed towards the accomplishment of this object has culminated in the discovery and application of a method for producing typographic printing plates by the aid of the photograph and the action of light on gelatine and bichromate of potash. The products of this art, which are now becoming somewhat numerous, are good, or nearly good enough for all practical purposes when the original is itself a printed picture; but the engravings produced by this method from drawings are frequently unsatisfactory unless a degree of finish, that can only be attained by long practice and great labour, has been employed in the preparation of such drawings.

Still another class of experiments, and the one to which I desire to call your special attention, is based on the employment of drawing implements, acids, and tools for the purpose of creating a raised surface on a metal plate that corresponds in its inequalities with the lines of a wood engraving. In France a great deal of attention has been paid to this system of operations during the last thirty or forty years, and M. Gillot, who died but a few months ago, brought the art of engraving with acids on zinc to such a state that it has been employed for many purposes, and resorted to with great frequency, especially for illustrations of an inferior grade, which it was desirable to produce with great rapidity and cheapness.

M. Gillot demonstrated that if a drawing is made on a piece of polished or grained zinc with a pigment or substance sufficiently powerful to protect the lines drawn from the action of acid, the whites of a picture may be eaten away by acids to a sufficient depth to afford the relief necessary for a typographical engraving, the acid thus doing the work of the graver; and this principle of production being established, the details to be perfected relate to the substances to be used in drawing, the methods of applying them, and the selection and management of acids during the process of engraving.

A somewhat detailed description of the Gillot process will be found in an article published in the *Printers' Circular* of this city for October, which I contributed to that journal, and it is therefore unnecessary to describe it more fully here.

One of the characteristics of the engravings produced by the Gillot process, which it seemed to me desirable to avoid, was their want of resemblance to wood engravings. Although printed on typographic presses, many of the specimens I have seen looked more like inferior lithographs than wood engravings. This peculiarity I believe I have fully succeeded in avoiding. You may consider the pictures good, bad, or indifferent, but very few persons would suppose they were produced by any other process than wood engraving; and the pictures themselves can be made as good as the art work employed in their preparation.

One of the most embarrassing difficulties involved in all attempts to produce acceptable substitutes for wood engraving arises from the great variety in the depths of the different portions of the plate or block from which impressions are to be made. It is easy enough to make all the

\* Read before the Franklin Institute.

black lines necessary to produce a printed picture; but one of the most serious tasks is to get rid of all the superfluous wood or metal that must be removed before the parts intended to be white can escape the searching touch of printers' ink. The slightest scratch on a space surrounded by the black parts of the picture will create a white mark, while indentations of considerable depth are required for all whites of considerable breadth—the general rule being that each enlargement of the area of the white portion of a picture requires a corresponding increase in the depth of the block or plate from which impressions are taken. Wood engravings are made up of a series of black and white lines, and the essential requisite in their production is the arrangement of these lines in appropriate artistic harmony, and with due regard to the effect requisite for the proper representation of the object to be illustrated. In many wood engravings the principal portion of the picture consists of a series of white and black lines or surfaces, which do not at any point possess any considerable depth, or occupy any considerable area of the plate; and it occurred to me that many pictures, good enough for practical purposes, could readily be produced by creating, mechanically, on a plate a series of straight black and white lines, as the basis or substratum on which any desired design could be drawn.

This idea I have practically applied to the production of a considerable number of engravings intended for various purposes, and impressions from these engravings have been taken on all the leading varieties of typographical presses.

Mr. Ringwalt then read the specification of his American patent, as giving a terse description of the process.

The object of my invention is to produce quickly, and at a cheap rate, plates from which pictures may be made by an ordinary typographic printing press, and this object I attain by drawing on a varnished and scored plate, with acid-resisting varnish, the picture to be produced, and then subjecting the plate to the action of appropriate acid.

In carrying out my invention, the first thing to be done is to select a metal plate of proper size, having a perfectly plane and smooth surface. I prefer, both on the score of economy and efficiency, ordinary sheet zinc. I first cover the plate with a thin coat of varnish, or other material capable of resisting the corrosive action of the acid to which it has to be subsequently subjected. I then, by means of a ruling machine, score the entire surface of the plate. \* \* \* The varnished surface of the plate may be scored with any system of lines which the character of the picture to be produced may suggest, the scoring determining the style of groundwork of the picture. After the varnished plate has been thus scored it is ready for the artist, who proceeds to paint with a resistant varnish on the scored surface the design or figure he desires to produce. \* \* \* At the points where high lights are required, the varnish is scraped away, and the metal surface of the plate exposed to an extent and form determined by the character of the lights. The plate is now subjected to the action of dilute nitric or sulphuric acid, or other corroding bath usually employed in etching, the acid eating away all the parts of the metal exposed. When this process has been completed, the varnish is removed from the face of the plate, and the latter is then mounted on a block of appropriate thickness, and this block may be used for printing from in an ordinary typographical press, the ink adhering to those parts only of the plate which had been covered with the varnish. The impression taken from the plate will consequently be precisely like the varnished portion of the same. \* \* \* More elaborate plates may be produced by varying the character of the scoring in a manner which yet nature of the picture to be produced may suggest.

## THE PREPARATION OF DIFFRACTION GRATINGS.

BY LORD RAYLEIGH, F.R.S.

[We have been favoured by Lord Rayleigh with a copy of his communication to the *Philosophical Magazine* on the subject of the manufacture and theory of diffraction gratings. We reprint those portions of especial interest to many of our readers.]

There are two distinct methods of copying practised by the photographer—(1) by means of the camera, (2) by contact printing. The first, if it were practicable for our purpose, would have the advantage of leaving the scale arbitrary, so that copies of varying degrees of fineness might be taken from the same original. By this method I have obtained a photograph of a piece of striped stuff on such a scale that there was room for about 200 lines in front of the pupil of the eye, capable of showing lateral images of a candle; but I soon found that the inherent imperfections of our optical appliances, if not the laws of light themselves, interposed an almost insuperable obstacle to obtaining adequate results.

However perfect a lens may be, there is a limit to its powers of condensing light into a point. Even if the source from which the light proceeds be infinitely small, the image still consists of a spot of finite size, surrounded by dark and bright rings. That this must be so may be shown by general considerations without any calculations. If a lens is absolutely free from aberration, the secondary waves issuing from the different parts of its hinder surface agree perfectly in phase at the focal point. Let us consider the illumination at a neighbouring point in the focal plane. If the distance between the two points is so small that the difference of the distances between the point under consideration and the nearest and furthest parts of the object glass is but a small fraction of the wave-length ( $\lambda$ ), the group of secondary waves are still sensibly in agreement, and therefore give a resultant illumination the same as before. At a certain distance from the focal point the secondary waves divide themselves into two mutually destructive groups, corresponding to the nearer and further parts of the object glass. There is therefore here a dark ring. Further out there is again light, then another dark ring, and so on, the intensity of the bright rings, however, rapidly diminishing.

The radius  $r$  of the first dark ring subtends at the centre of the lens an angle  $\theta$  given by

$$\sin \theta = \cdot 61 \frac{\lambda}{R},$$

where  $R$  is the radius of the lens. If  $f$  be the focal length, we have

$$r = \cdot 61 \frac{f\lambda}{R}.$$

Let us now suppose that the problem is to cover a square inch with 3,000 lines. On account of the curvature of the field, it would be impossible to obtain extreme definition over the surface of a square inch with a less focal distance than (say) four inches. If we take

$$f = 4 \text{ and } \lambda = \frac{1}{40,000},$$

we find

$$R = \frac{\cdot 61}{10,000r},$$

which gives

$$R = \cdot 2 \text{ for } r = \frac{1}{2,000}.$$

That is to say, if the focal length were 4 inches, and aperture  $\cdot 4$  inch, the first dark ring corresponding to one of the lines would fall on the focal point of the neighbouring one—a state of things apparently inconsistent with good definition. It is true that the aperture might well be greater than half an inch, so that it may seem possible to satisfy the requirements of the case. But the result of the above calculation, being founded on the supposition of entire freedom from aberration, both spherical and chromatic, is subject in practice to a large modification. In astronomical telescopes, where everything is sacrificed to the requirement of extreme definition at the centre of the field, the theoretical limit is sometimes closely approached; but the case is very different with a photographic lens; in fact, the very first thing it occurs to a photographer to do, when he wishes to improve the definition, is to contract the aperture of his lens by

means of a stop—a course which would be attended with the opposite result in the case of a perfect object glass, or even a good astronomical telescope. While, therefore, it might be too much to say that the reproduction of 3,000 lines in an inch by lens and camera is impossible, the attempt to do so without very special appliances appears in a high degree unpromising. It would certainly require a lens more than usually free from spherical aberration, and unlike either a telescopic or a photographic object glass,\* achromatic (if the expression may be allowed) for the chemical rays unless, indeed, the latter requirement could be evaded by using approximately homogeneous light. It must be understood that nothing is here said against the practicability of covering a small space with lines at the rate of 3,000 to the inch, a feat probably well within the powers of a good microscopic object glass.

The method of contact-printing, on the other hand, is free from optical difficulties. The photographic film prepared on a flat piece of glass (or other support) may be brought by moderate pressure in a printing-frame within a short distance of the lines of the original grating; and if the source of light be moderately small, and the rays fall perpendicularly, the copy rarely fails in definition, unless through some photographic defect. When direct processes not depending on development are employed, the unclouded light of the sun is necessary. To avoid too much diffused light, I usually place the printing-frame on the floor of a room into which the sun shines, and adjust its position until the light reflected from the plate-glass front is sent back approximately in the direction of the sun. Too much time should not be lost in this operation, which requires no particular precision. Usually I cut off part of the extraneous light by partially closing the shutters; but I cannot say whether this makes any difference in the result. Those who are accustomed to this kind of experimenting will know that it is often less trouble to take a precaution than to find out whether it is really necessary. In an early stage of an investigation, when the causes of failure are numerous and unknown, it is best to exclude everything that can possibly be supposed to be prejudicial. When the principal difficulties have been overcome, it will be time enough to determine what precautions are necessary, if the question has not been already settled by accidental experience.

(To be continued.)

### RECOVERING THE SILVER FROM PHOTOGRAPHIC WASTES.

MIXTURE OF IODIDES, CHLORIDES, CYANIDE, NITRATE OF SILVER, HYPOSULPHITE OF SODA, CYANIDE OF POTASSIUM, ETC.

BY JAMES CHISHOLM.†

VARIOUS methods have been proposed to accomplish this object, but every one of them suffers from disadvantage: one of them yields the sulphide of silver, which takes an enormous quantity of carbonate of soda to reduce, and repeated fusing; another method yields chloride of silver mixed with sulphur, where the difficulty is again the removal of the sulphur; another method, the reduction with metallic copper, is too slow and tedious. It was a particular study of mine to find a quick, accurate, and easy way to regain the silver from a mixture of all kinds of combinations, and at last I succeeded. As you are all well aware, the solution of chloride or iodide of silver in hyposulphite of soda deposits the silver combination on addition of acids, but, at the same, a great deal of sulphur, which mingles with the chloride of silver, and thus the regaining of the silver is rendered more complicated, a very large amount of carbonate of soda or potash being required to remove the sulphur, or a prolonged boiling with strong

nitric acid. I was convinced that in order to avoid the depositing of the sulphur, I had to destroy the hyposulphite in such a manner as to make the separation of sulphur impossible.

This I found may be accomplished by adding the silver refuse to warm strong nitric acid. No separation of sulphur thus takes place, because the hyposulphurous acid in a nascent state is at once oxidized into sulphuric acid, as is explained by the following equation:—

But here we have the development of very disagreeable fumes of nitrous acid and hydrocyanic acid from cyanide of potassium. This method seemed to me impractical. I found I could replace the nitric acid by a mixture of chlorate of potash with an acid, but even in this case we cannot avoid the evolution of offensive gases.

I saw I had to bring about the oxidation in an alkaline or neutral solution, and tried the effect of hypochlorite of lime and of soda, and succeeded. If hyposulphite of soda is added to hypochlorite of soda, an oxydation to sulphate of soda will take place. This may be represented by the following equation:—

No separation of sulphur takes place, and no development of any disagreeable fumes; and thus this method may well be recommended, and I am confident it will replace and supplant all others. The common bleaching powder (hypochlorite of lime) may do also, but for obvious reasons the hypochlorite of soda (freshly prepared), a clear liquid, is far preferable. I simply proceed as follows: I add to the silver refuse hypochlorite of soda, until the precipitate becomes permanent, and does not disappear by stirring the mass, and assumes a perfectly white colour. At this time a strong evolution of gas will ensue, which is perfectly odourless, consisting mainly of carbonic acid derived from the carbonate of soda contained in the hypochlorite.

Now I heat the mass moderately, and take a little of the supernatant clear liquor out, adding to this a few more drops of hypochlorite. If no turbidity is thus produced, the process is finished, and the entire white precipitate, after washing with water, fused with carbonate of soda and potash in a crucible, whereby the pure silver bullion is easily obtained. To prepare the hypochlorite of soda I found the following way the simplest and the best: Take of chlorinated lime twelve troy ounces; carbonate of soda, twenty-four troy ounces; water, twelve pints. Dissolve the carbonate of soda in three pints of water, with the aid of heat. Triturate the chlorinated lime, a little at a time, with small portions of the water, gradually added, until a smooth, uniform mixture is obtained. Mix this intimately with the remainder of the water, and set the mixture aside for twenty-four hours. Then decant the clear liquid, and, having transferred the residue to a muslin strainer, allow it to drain until sufficient liquid has passed to make, with the decanted liquid, eight pints.

Mix this thoroughly with the solution of carbonate of soda, transfer the mixture to a muslin strainer, and allow it to drain, adding water, if necessary, towards the close, until eleven and a-half pints of liquid have passed. Lastly, keep the liquid in well-stoppered bottles protected from the light. The liquid is the hypochlorite of soda, ready for use, which is explained by the following equation:—

A transparent liquid of a greenish-yellow colour, having a slight odour of chlorine, and a sharp, saline taste. Its specific gravity is 1.045. It rapidly discolourizes a solution of indigo, and produces a copious light brown precipitate with a solution of sulphate of iron.

\* Photographic lenses are corrected on the principle of making the "visual and chemical foci" coincident, which leads to a different construction from what would be adopted were the chemical rays alone attended to.

## THE PHOTOGRAPHIC SOCIETY OF LONDON.

IN the sudden collapse of the executive body of the Photographic Society, and the hopelessness of any further successful conciliatory steps being taken by which a fusion of antagonist elements might be brought about, and harmonious co-operation secured, it seems tolerably certain that entire re-organization must be the best, if not the only course open to the society. At the present moment all is chaos, and it is improbable that a legal quorum of officers could be formed to transact business of any kind in the society. The six nominees of the requisitionists are, it seems to be generally held, in a very doubtful legal position, if from no other cause than the fact that their final election was decided by show of hands instead of by ballot. All the old council, with the exception of two or three, have, we understand, either actually resigned, or expressed indisposition to take further action until some step for a complete re-organization of the council has been made by the general vote of the society.

It were a bootless task, now, to consider the causes which led to a renewal of hostilities at the last meeting, and issued in a severance wider than ever between the old body of officers and their opponents. An "Old London Member" suggests, on another page, that this fresh outbreak of hostilities was but the legitimate issue of the distrust which still prevailed on both sides. If this distrust existed, it is tolerably clear that harmony could not long have prevailed. If, as is alleged, combined action was again invoked on the evening of the fourteenth to secure a vote, if necessary in opposition to the council, it is clear that old officers were to be permitted to resume office only on condition that they agreed with the opposition in their view of the legality of certain proceedings. If what our correspondent terms a "vigilance committee" were to be kept in reserve, ready for action whenever the leaders of the opposition felt disposed to summon them, the old council would have been subject to a form of coercion most intolerable, and the more offensive because they could not stoop to meet it by any similar effort at combination. As we have said, any detailed discussion of the matter is useless now; we merely refer to it as illustrating and apparently confirming the statement of our correspondent, that a deep-seated distrust prevailing, rendered a patched-up peace impossible. It is equally unimportant to discuss, now, the question whether the president showed wisdom in his impulsive response to interrogation, or whether nothing in his official life became him so ill as the leaving of it. As regards the council, it

is probable that varied views prevail amongst different members, but we believe that they are, with unimportant exceptions, at one as to the non-resumption of office under existing circumstances.

In this uncomfortable state of things a thorough re-organisation appears to be the only course to save the society. The only question which arises is as to the best mode of setting about it. There are two ways: one is by an appeal to the members at large, and an election by their suffrages; the other is by calling a special general meeting, and deciding the future of the society by the vote of resident members. Both modes will, we believe, be brought under the consideration of the next meeting. A communication from Mr. Hooper informs us that he contemplates moving a resolution to the following effect:—

"That in the present crisis in the affairs of the London Photographic Society, as at the present moment there is no legally constituted executive (the old members of council having, with one or two exceptions, resigned, and the six gentlemen who have been conducting the affairs of the society having been re-elected by show of hands instead of by ballot, as required by the laws), it is hereby agreed that the best way out of the difficulty will be to send round to all members of the society—country as well as metropolitan—an entire list of the subscribers, and request such members to attach a mark to the names of those gentlemen they wish to be the executive for the time being, taking care to elect one president, three vice-presidents, and eighteen councilmen; placing a "P" against the name for the president, a "V P" for the vice-presidents, and a "C" for the councilmen; and that these gentlemen shall be requested to meet and frame new laws—the same to be submitted to a special meeting, and on being discussed and agreed to, and printed, a general election of all officers shall at once take place, and shall be declared to be the legally constituted executive of the society until the following annual meeting."

This, in effect, is similar to the recommendation of a correspondent on another page. As regards the other proposition, a notice has been sent out by Mr. Spiller, as one of the vice-presidents, to the following effect:—

A special general meeting of the Photographic Society will be held immediately after the close of the next ordinary meeting, on Tuesday the 12th of May:—

1st. To substitute for the third, fourth, and fifth paragraphs of Law VII., enacted at the special general meeting of February 10th, 1874, the following:—

"If vacancies occur by death, resignation, or other cause in the office of president, vice-presidents, treasurer, secretary, or members of council, individuals shall be elected at the annual general meeting, or at a special general meeting to be called for the purpose, to fill the vacant places, and shall serve the offices subject to the condition of retirement by seniority that would have applied to the persons whose seats they fill.

2nd. And, in the event of this alteration of the clauses being carried, to nominate a president, three vice-presidents, and eighteen members of council, including a treasurer and secretary, to fill vacant places; such officers and members to be elected at another special general meeting, to be called at the earliest practicable date subsequently. JOHN SPILLER, *Vice-President*.

In both cases, it will be seen, the election of an entirely new staff of officers is contemplated; but in one case it is proposed that the election shall be by the whole body of the members, and in the other by the personal votes of those who can attend a special meeting. In neither case can the proceedings be conducted in conformity with strict law, as it is doubtful whether a legally-constituted quorum of officers can be formed to give legal effect to any proceedings. In Mr. Spiller's announcement, however, the precedent of law is followed, but it is, we fear, the narrow and imperfect portion of the law to which so much of the mischief and heart-burning of the late strife has been due, that portion of the law which has vested in the hands of a few resident members the control of a society which represents the United Kingdom. In Mr. Hooper's proposition we have the difficulty boldly recognized and met. The reign of law being suspended, appeal is to be made to

the legitimate source of law, the body politic, in whose behalf the laws have to be made. Every well-wisher to the society must desire an end to those miserable bickerings. The voice of the society at large will be accepted as decisive, we opine, on all hands, whilst the decision of a meeting of resident members is as little likely to settle anything satisfactorily and permanently as any of the recent meetings, and every step of the kind must tend, more and more, to give a merely local character to the action of a society which should be representative and national.

#### PRESERVING SENSITIVE PAPER.

THE preparation of sensitive paper which may be kept without discolouration continues to interest photographic experimentalists in America. At a recent meeting of the Photographic Section of the American Institute, Mr. A. T. Anthony exhibited a sample of paper which might be kept several days without deterioration. The bath was made as follows:

"Put thirty grains of nitrate of silver in one ounce of water. To that add two grains of citric acid. After that is dissolved, add ammonia until the precipitation—which is a precipitate of the citrate of silver—ceases. Then re-dissolve with nitric acid, and leave the solution so that a small proportion of the citrate of silver remains. Let that settle perfectly, and then add ten drops of nitric acid to every two quarts of the solution."

The prints were said to be delicate and vigorous, and in every way satisfactory. Mr. Anthony added:

"The print had been fumed ten minutes with strong ammonia. He had kept similar paper for five days just as white as when it was made. The paper comes from the bath more glossy than it goes in. The bath is acid, and does not turn. It becomes saturated with albumen to a certain point, and then takes up no more from the paper. He published an account of this some time since, and the *Photographic News* and the *Bulletin* of the French Photographic Society regarded it as merely experimental and empirical. He inquired whether there was anything photographic which was not empirical. Chemicals could be combined according to the known laws; but no one could predicate the action of light upon any new combination of chemicals; and any combination of chemicals in connection with the action of light must be empirical. The paper was sensitized in a light room. He could float a hundred sheets in the solution without having a single bubble. If a bubble forms, it breaks readily. The paper is more sensitive in printing than ordinary paper, and tones splendidly."

We do not remember to have made any slighting remark on Mr. Anthony's experiment. Of course almost everything in photography is empirical. Very little is understood of the rationale of old processes, much less can we hope to predicate with exactness the possibilities of new processes, or to limit results by theoretical considerations.

#### A NEW METHOD OF RETOUCHING AND ENLARGING COMBINED.

In the *Moniteur de la Photographie* reference is made to a new process just patented in France under the name of "Lambertypie." It appears that in the course of 1872 some enlarged portraits, finished in a new style, caused a sensation in Paris, and MM. Lambert and Vuillier, by whom the process had been elaborated, decided not to take out a patent for the same, but preserve the method a secret, and work it for themselves. The partnership, however, came to nothing, and M. Lambert has now patented the process, and announces himself ready to grant licenses to any one desirous of making use of the process.

Unfortunately we are, as yet, without any precise information upon the subject of the process, but so far as the enlarging goes, this seems to be carried out by the aid simply of carbon transparencies. M. Lacan, who recently

paid a visit to M. Lambert's studio, states that the working apartment is fitted up as a dark room, with yellow glass, a camera looking out through one of the panes which had been removed. Outside, a large mirror, moving vertically, served as reflector, and in the interior of the camera were frames for transparencies.

During M. Lacan's visit, M. Lambert collodionized a plate of sixty centimetres, and secured an enlargement from a transparent carbon positive in six minutes (it being half-past five in the evening); he eschewed all intensifying, and his image was rather a weak one. Up to this point there was nothing of novelty, but it is at this point that the retouching takes place by a method which is said to be very simple and practical, and transforms the image at once into a beautiful picture.

It is stated that an artist will naturally produce finer effects than one unused to the brush, but a little practice will ensure very passable results.

#### PROTECTING PHOTOGRAPHS FROM ATMOSPHERIC INFLUENCES.

A CORRESPONDENT at Canterbury (Mr. Joseph Peach) suggests, as a means of securing permanency in valuable photographs, that they should be mounted and framed so as to be impervious to moisture, dust, foul gases, and other deleterious atmospheric influences. There can be no doubt that many a spoiled good picture owes its fading and discolouration to the utter lack of proper care in its preservation. Imperfectly fixed and imperfectly washed prints will fade, no matter how carefully they may be preserved; but where a print has been carefully treated in each stage of its production, hermetical sealing from the atmosphere will doubtless prolong its tenure of existence. The method our correspondent describes as follows:—

"Instead of mounting on the usual (sheet of destruction, I term it) cardboard, take a sheet of thin flat glass, tip the back corners of the print with a solution of glue, lay it on the glass in position. Another sheet of glass, exactly the same size, is laid on the print; bind the two glasses together round the edges with stout gum paper. When dry, coat the paper binding two or three times with shellac spirit solution. The print thus permanently hermetically sealed up, lay it thus prepared in its frame—black ebony, let me say. Next lay on a piece of crimson velvet, or any such material as will suit the taste, then a sheet of paper, if necessary, and lastly the back-board; fasten with sprigs. The print will, at a distance, have the appearance of being mounted on the velvet."—Yours most respectfully,  
JOSEPH PEACH, |  
3, Bingle Street, Canterbury.

#### ON THE TREATMENT OF ALBUMENIZED PAPER.

BY L. G. KLEFFEL.

COMPLAINTS innumerable, to be heard from time to time, against samples of albumenized paper, have caused me to institute a series of investigations in reference to the material, for I could not, somehow, bring myself to believe that defects which are so often inveighed against were all of them due to the paper itself. My opinion seemed all the more plausible by reason of the fact that, while one description of paper found favour with some, by others it was utterly condemned. The question of blisters I left out of the question altogether, for this defect is only met with when the albumen film, as in the case of very brilliant papers, is very thick indeed.

The result to which I have been led by my experiments is, that the faults which are most generally found in albumenized papers are not due to the material itself, but are, in the main, caused—

a. By the employment of weak silver baths; and  
b. By faulty manipulation of the paper in the operation of sensitizing.

As is well known, the white of egg is an alkaline body

capable of being dissolved in water. Of this one may easily convince oneself by immersing a strip of albumenized paper in water for five minutes, and then drying it on filter paper, when its gloss will be found to have vanished. By the use of a solution containing silver, the albumen is coagulated—or, in other words, transformed into a condition which hinders its solution—and the coagulation is the more complete the more silver there is contained in the liquid, that is to say, the stronger the solution of silver chances to be. From this it follows, as a matter of course, that the weaker the sensitizing bath is, the greater is the risk of the albumen surface being dissolved, causing the finished prints to be mealy and woolly; in many cases, when the bath contains a large proportion of albumen, the pictures are without gloss, and appear to be almost in a fog.

In order to bring about the coagulation of the albumen with perfect certainty, the silver bath should never be weaker than one in twelve, every ounce of fluid containing forty grains of nitrate of silver. Far better, however, is it to have the proportion of one in five, or in the ratio of one hundred grains of nitrate to the ounce of water, for by this means not only is the defect in question rendered perfectly impossible, but one is, moreover, not called upon to strengthen the bath continually as it is used, it being quite safe to allow the strength of the solution to diminish to one in twelve without fearing any injurious results therefrom. The best results are, however, of course, only then secured when the bath is kept in its normal state by the constant addition of silver. This is easily done, as it is a known fact that every sheet of albumenized paper measuring eighteen by twenty-two requires for the formation of chloride upon its surface about thirty grains of nitrate of silver, and this amount is absorbed from the bath, whether it is one in twenty, or one in five. For every sheet that is sensitized it is only necessary, therefore, to add to the solution thirty grains of nitrate of silver.

The argument that the employment of a very strong silver bath is much more costly than a weak one is to a great extent illusory, for, as we have just seen, the same quantity exactly of silver is required to form the sensitive film, whether the silver bath is strong or weak, provided that the percentage of salts contained in the albumen is the same. If, for instance, we have to do with a bath containing sixteen ounces of silver solution, of a strength of one in sixteen—which will contain, therefore, 180 grains of nitrate of silver—the bath will become entirely exhausted after sixteen sheets of paper have been sensitized upon it; as each sheet would take up thirty grains, the whole amount of silver would be withdrawn, for 16 by 30 equal 480, and it is this amount exactly which would be absorbed from even the strongest bath.

Then it is further argued that the solution which adheres to the surface of the paper when this is lifted from the bath must also be taken into consideration in determining the cost of the operation. This is, of course, a point that cannot be gainsaid. At the same time, the loss in this direction will disappear almost altogether if a glass rod is employed for draining the paper, for after the latter has been drawn over the rod, there will remain scarcely a superfluous drop of liquid attached to the paper. But in the case even of the pictures being somewhat more costly of production by the employment of a strong silver solution, there are very few photographers who would grumble at the slight increased expense, if thereby their pictures would be guaranteed to them perfectly clear and bright. By having recourse to a strong silver bath the many defects complained of are obviated, especially when the operation of floating the paper is confined to as short a period as may be absolutely necessary, and not continued, as is the case in some studios, for a period of four or five minutes. Irrespective of the circumstance that much time is necessarily lost in this way, there is always the danger

of the albumen becoming dissolved. The silver solution also penetrates into the body of the paper, and causes, in printing, the image to sink into the material, and it does not remain, as it should do, upon the glossy surface of the albumen. Only by floating the paper on the solution for the shortest time possible can the brilliancy and beauty of the negative be most fully rendered.

As a proof of this may be advanced the circumstance that if a sheet of albumenized paper is floated for about fifteen minutes upon a weak bath, the albumen becomes in this time completely dissolved, and the paper loses its gloss entirely. Long floating on the bath has, moreover, the disadvantage of speedily discolouring the bath, from the fact that the more albumen becomes dissolved in it, the more rapidly does the bath assume a brownish colour.

As the formation of the sensitive chloride of silver film commences as soon as ever the paper comes into contact with the silver bath, it is only necessary to allow the albumenized paper to float until it touches the solution uniformly all over—a circumstance which takes place, at the most, within thirty or fifty seconds after the paper has been applied.

If, therefore, my brother photographers will only resolve to stand fast by these precepts, they will not only cease to complain of bad samples of albumenized paper, but they will save themselves much worry and anxiety, and be rejoiced with the beauty of their results.

#### A NOVEL PLAN OF PRODUCING CARBON PRINTS.

BY M. FARGIER.\*

A LITTLE while ago I had the honour of forwarding to the French Photographic Society some photographs printed in pigments obtained by a new method of operating, which I will now proceed to describe.

In one hundred grammes of water I dissolve five grammes of perchloride of iron and five grammes of citric acid. I pour this solution into a bath, and float upon it, for the space of a minute, a sheet of paper of very fine texture. After drying in the dark, I expose the paper to light under a negative. I then immerse the print as it comes out of the frame in a bath of pigmented gelatine, or gum, containing a trace of bichromate of potash. I wash immediately afterwards in tepid water if gelatine is contained in the bath, but if it is gum, then cold water is employed.

In this way the image is thoroughly cleansed of the colouring matter, and there remains but to fix it, free it from oxides, varnish it, &c. To every cubic centimetre of coloured gelatine, or gum solution, I add one drop of concentrated solution of bichromate of potash. If this amount be exceeded, the image produced lacks vigour; and if it be diminished, then the picture suffers in washing.

It would, perhaps, be preferable to employ, instead of coloured gelatine solution, the pigmented paper, or tissue, made by M. Marion, a material which is moistened with bichromate solution, and then applied to the face of the dry print.

The reactions that occur in this process are easy to understand. The light reduces the perchloride, and transforms it into proto-chloride, and this reduces the bichromate, and transforms it into sesqui-oxide of chromium, which combines with the gelatine, and renders it insoluble. Again, the citric acid accelerates in a great degree the action of the light, and opposes the action of the perchloride of iron upon the gelatine in the whites of the image.

I must admit that the process is one not unattended with difficulty, and that it is, moreover, scarcely one that will interest the general photographer.

\* Bulletin de la Société Française.

## AGAINST WEAK PRINTING BATHS.

BY JOS. UNGAR.\*

DISSOLVE one part of nitrate of silver in six parts of distilled water, and recruit it, according to daily use, by a solution of one part of silver in four parts of water, and you will have an excellent, trustworthy, and enduring sensitizing bath for paper. This formula, it will be said, is a very old one, and has been repeated times without number. True enough; but if the stone is continually rolling down hill, it must be pushed up again and again. One would scarcely believe it, but it is a fact that there are numbers of theoretical economists who, notwithstanding repeated failures, still keep to a weak silver bath, only giving it up to try one weaker still, with admixture often of foreign compounds, whose influence upon photography not a soul of us has an inkling of. That the results are not of the best; that the beautiful shining albumenized paper prints are flat; that defects arise upon the slightest inattention; that the bath rapidly becomes unserviceable by the deposit of organic matter, and requires elaborate measures to restore it; that the liquid in a short time goes the way of all chloride; and finally, that a great deal of time is lost over the business, which to the photographer, more than another, signifies money—all these are matters of which theorists of this kind take no account. And these gentlemen never see that it is they themselves who suffer, because, instead of producing from the finest negatives brilliant and deep toned photographs, they give the public matt pictures of poor appearance. That they gain nothing in the end by their parsimonious behaviour they can rest assured.

Those who allow their paper to float upon such a bath as here referred to, for the space of two minutes, and then remove the sheet gently, and hang it upon clips to dry spontaneously, will be sure to secure a vigorously printing and sensitive paper, provided the raw material itself and the albumenizing are faultless. Contrarily, if with such a sensitizing bath no good prints can be obtained, then one may be quite convinced that the paper itself is of inferior quality.

Slow and careful withdrawal of the paper from the bath is to be recommended, because in this way very little of the superfluous liquid is taken away, and the volume of the bath, therefore, but very slightly lessened. It will be found that only a drop or two of moisture passes to the bit of blotting-paper attached to the corner of the hanging sheet, while otherwise an appreciable amount of liquid will be lost.

To prevent any tendency to break, the paper is folded as soon as no more moisture is observed upon the surface of the sheet, and before it has had time to become dry and hard, and has rolled up stiffly, the material being put away flat in such sizes as may be desirable. Strong baths require that the albumenized paper should not be perfectly dry before being sensitized; for this reason, it is well to let the paper remain at least twenty-four hours previously in a damp locality, taking care, however, that it does not come into actual contact with water. Should there be no opportunity for doing this, and should the paper, after being floated on the bath, show signs of repelling the nitrate solution in parts, and drops be formed on the albumenized surface, the best plan is to place the sheets face upwards, after sensitizing, upon paper; to put over each a piece of clean filter paper, which absorbs the moisture very readily, the sheets being hung in this way upon clips, and dried. This plan of proceeding does not hinder work in the least, because it can always be done while the next sheet is floating upon the silver bath. The first method is the preferable one, although the latter is one often pursued in large studios.

Another plan I adopt of working a paper which has become too dry is one I can warmly recommend: it is

simply breathing upon every sheet before it is sensitized. The plan of proceeding is the following:—The dry, rolled-up sheets of paper are taken up like a pea-shooter, and, first from one side and then from the other, breathed into, the warm air being prevented from escaping by the operator placing his hand on the other extremity. The paper is then rolled up a second time, differently from the first, and again moistened with the breath, so that all portions of the surface are acted upon by the moisture, and then it may safely be sensitized. The action is marvellous. A sheet of paper not so treated will allow the solution to dry in drops upon its surface, while simply breathing upon will remedy the defect. The plan is as simple as it is effective, and will be prized by all who do not possess a cellar for keeping their paper in, nor a moist or cool locality for sensitizing. It should be borne in mind that the bath must be always brought up to its normal strength every day by the addition to it of a proportional quantity of the stronger stock solution.

One main advantage of a short sojourn upon a strong bath lies in the circumstance that upon such papers the print remains on the surface, and thereby the deep toned shadows and delicate gradations of the negative are enhanced, whilst the shadows upon paper prepared with a weaker bath possess neither vigour nor fine details, and have a flat, washed-out look. If it is sought to obviate this defect by a longer floating upon the bath, more vigour is secured thereby, it is true, but then a portion of the albumen film is dissolved away, and the surface loses much of its glossy character. The silver sinks deeper into the paper mass, and the picture, therefore, appears more sunken, and loses its delicacy.

The operation of sensitizing upon strong baths is, moreover, comparatively easy. Failures in preparation are more rarely met with. Any bungling when placing the paper on the liquid does not leave a mark, and if air-bubbles are formed by letting it fall upon the solution too rapidly, these are rapidly dissipated by lifting the opposite end from the bath and allowing it sink again. With weaker solutions the matter is different, the sensitising operation being somewhat risky. A pause in laying down the paper inevitably produces a matt insensitive line, and if bubbles are formed, no matter how soon they are chased away, small circles are apparent on printing. The explanation of these disagreeable defects is easy to discover. The sensitizing process is of a very energetic nature. A strong bath coagulates the surface of the albumen in a moment. The large quantity of silver at hand eagerly combines with the salts. In a weak bath the action is slower, but still quick enough to rob the surface of the bath, instantly, of the greater portion of its silver. If that portion of the liquid containing little silver comes into contact with a not coagulated part of the paper which has been covered by an air-bubble, the albumen must be in a great measure dissolved by the bath, leaving that part of the surface with very little silver upon it. The necessary consequence of this is, not only the destruction of the paper on such spots, but also a certain deterioration of the bath.

It may be advanced by some that they are careful, and take the greatest pains in the sensitising of the paper. This will not, however, advance matters much, for even in this case a certain quantity of the albumen is dissolved in the bath, because the coagulation takes place so slowly and imperfectly, as may be proved by the flat prints which result. If greater vigour is sought to be secured by increasing the period of sensitizing, it would either be necessary to lengthen the time progressively until a space of ten or fifteen minutes is reached, or to add as much silver solution from time to time to the bath as is required in the case of a stronger liquid.

Dilute baths usually deceive a tyro, because a first experiment is no criterion of their value, the sheets sensitized at the commencement giving very good impressions. But

\* *Photographisches Notizen.*

it is not long before one is beset with difficulties. Manufacturers of paper who give their customers a formula for the preparation of a weak bath have presumably made an experiment with it, and been contented with the first results furnished by the bath, and they are, therefore, considerably astounded when their good paper is subsequently thrown back upon their hands as altogether un-serviceable. It is only a practical man of experience that can form an opinion on matters of this kind.

Economists may still put forward their belief in a weak bath and subsequent ammonia fuming, and in adopting this method there is, we must admit, a saving to be experienced. But this plan has also its drawbacks: loss of time during sensitizing and fuming is involved, and much caution is necessary, in the latter operation, not to allow the ammonia to act too long or too briefly upon the paper, as otherwise the tone and vigour of the prints will be very uneven. To the unhealthy character of the ammonia fumes attention should also be called, only photographers are so used to noxious vapours of all kinds that one more or less is of little moment.

To summarise, when we know that a concentrated silver solution never can get out of order, and is a guarantee always for good work; when we know that paper sensitized with it tones beautifully and uniformly in every neutral gold bath; when all operations are thus simplified, and material saved; in short, when in every respect better results are obtained, ought we to continue to bother ourselves with weak baths? Assuredly we think not, and it is to be hoped that the reader is of the same opinion, and will not carry economy so far as to become a vice rather than a virtue, leading in the end to an excess of expenditure rather than anything else.

### Correspondence.

#### THE CRISIS IN THE PHOTOGRAPHIC SOCIETY.

SIR,—In your recent comments on the proceedings of the last meeting of the Photographic Society you refer to the sudden renewal of hostilities as the result of a jealous predisposition to take offence on both sides, and you imply that it Mr. Hughes had not asked just at that juncture for explanations as to the position of the "six" on the one hand, or had not Mr. Glaisher "cut up rough" on the other, all might still have been harmony and peace. But, sir, I venture to suggest that in this view of the case the symptoms are mistaken for the cause. Both the things referred to were but the outward and visible signs of a state of feeling on both sides which would have rendered harmonious co-operation impossible. The truth was, that mutual confidence had been destroyed, and whilst outward appearance of reconciliation had been made, distrust really seems to have prevailed on both sides.

What but distrust could have prompted the original initiators of the agitation to summon together their forces for combined action, as I am informed they did? What but distrust could have prompted Mr. Glaisher to claim a unanimous vote from the meeting before he would take the chair? This distrust prevailing, another disruption, sooner or later, was probably inevitable: but it was precipitated by Mr. Glaisher's hasty and unreasonable bearing, by which he lost all the vantage ground for himself and the council which they had hitherto possessed. He held the sympathy of the members at large as an earnest, energetic president, who, in return for zealous service, had been insulted, at the February meeting, in a manner which the malcontents themselves, almost to a man, condemned. The society at large sympathised with him, and with the council who resigned with him. Even with the knowledge that an antagonistic combination existed in the meeting, had he answered the interrogation as to the "six" with any reasonable explanation, it is probable the meeting would have been with him. But, unfortunately, he (to use a slang phrase) "lost his head." The interrogation coming from the same gentleman who had impeached the council in February probably revived all the bitter recollection of the insults heaped on them on that mischievous evening. At any rate,

he took counsel with anger instead of reason, and vehemently declared his resolve not to sit with the "six."

Your conjecture, sir, that as to his alleged objection, that none of the six was a nominee of the council, there must have been some misunderstanding, is, perhaps, ingenious, but, I am afraid, not correct. Whatever he meant, there can be little doubt that this was what he said; and by saying it, and saying it in such an offensive manner, he succeeded in alienating the sympathies of the whole of the meeting. If the members of the council do not endorse his words and action in this matter—and I cannot conceive that they do—they are in a very unfortunate position, especially if, as you have suggested, they are impelled by *esprit de corps* to stay by a leader whose action they condemn. If, when questioned about the "six," Mr. Glaisher had courteously explained that no disrespect was intended to these gentlemen or to the meeting which had elected them, but that the mode of their election was not *en règle*; or if he had said the old council had been asked to "resume" office, and a resumption meant taking the thing up at the point at which they had left it, and that this necessarily involved a restoration of things in *statu quo*, without conditions, and that these six, having been irregularly elected in the interregnum, the old council had no power of recognizing them—if, I say, some courteous and reasonable explanation had been offered, it is probable that the meeting would have been with him, and a rupture would have been avoided.

I am free to admit, however, that with the impression on their minds that the opposition combination had been again summoned to force these "six" into the council, whether the old members of the council accepted them as legal members or not, no real harmony could be expected. If the old council had resumed duties on conditions dictated by the opposition, they might, indeed, have been charged with "clinging to office." Besides, no free action could have taken place in the council if they knew that a "vigilance committee" could be summoned at any moment to act in organized opposition to any steps they might not approve.

What, then, can he do to save the society? The only remedy I can suggest is a short and sharp one: it consists in beginning *de novo*. I have no faith in tinkering. The demon Distrust must be exorcised. The opposition have not complete trust in the old council: the council have not trust in the opposition. And any patched-up peace, any fusion of parties, must issue in failure. When such a state of things prevails in the imperial government, there is but one course, and that is appeal to the country. An appeal to the whole of the members would doubtless satisfy all parties. Any officer elected by the suffrages of all the members would legitimately represent the society, and would cease to represent either the council or the opposition, even if he had been identified with the one or the other before. For these reasons, in this emergency, I recommend at the earliest date a general election. The law (practically) provides for election by the votes of resident members only. It is upon this rock the society has split, and as all law seems to be at an end, this precedent should be ignored, and common sense and good feeling consulted in the appeal to every member of the society.

—Yours obediently,  
AN OLD LONDON MEMBER.

### Proceedings of Societies.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this association was held on Tuesday evening, the 28th ult., at the Free Public Library, the Rev. T. B. BANNER in the chair.

The minutes of the previous meeting were read and passed.

Mr. WILKINSON exhibited a number of negatives taken on plates prepared by Mr. Bolton's process. He had succeeded very well with them, but, on varnishing with spirit varnish, the film—owing, no doubt, to the soap in it—rose in small blisters and spoilt the negative. Other varnishes might be used to avoid this.

In reference to two exceedingly fine transparencies which were handed round,

Mr. W. ATKINS made the following remarks:—"At our January meeting I brought for your inspection a number of transparencies prepared by Mr. Bolton's new process. I then stated that Mr. Bolton had prepared, in my presence, a dozen plates in the very short time of seventeen minutes. Five of those plates were used

for transparency printing the same evening; the rest have since remained by me. With the object of again drawing your attention to this important process, I have this evening brought two transparencies in order to afford you an opportunity of judging of the keeping qualities of the emulsion. The previous pictures exhibited were prepared on the 10th of January, from an emulsion made by Mr. Bolton about three weeks previously, and it will, perhaps, be remembered that the exposures given ranged from six seconds to a fraction of a second to gaslight, the object being to test crucially the rapidity of the process. With a moderately dense negative five or six seconds was found to be quite long enough. Since that time, owing to business engagements, I have been unable to do anything in photography until last evening, when I printed the two transparencies I now lay before you. No. 1 is a plate prepared by Mr. Bolton in January, the emulsion being then three weeks old. This plate was exposed under a rather dense negative for ten seconds, the development being effected with a three-grain solution of pyrogallie acid, four drops of a five-grain solution of bromide of potassium, and four drops of ammonia solution (one part of ammonia to twelve of water). No silver was used to intensify, nor any gold to tone it. Plate No. 2 was coated and dried last evening from the remains of the emulsion used by Mr. Bolton on the previous occasion. This has remained in my possession since January, and has been untouched, except to shake it up occasionally. This plate was exposed under the same negative as No. 1, receiving identically the same exposure and development, the final result showing not the least difference between the two plates. The emulsion used is now eighteen weeks old, and has lost none of its original good qualities. It can, I think, be fairly claimed that, having stood the test so long, it will keep indefinitely."

The Rev. H. G. PALMER exhibited some collodio-albumen negatives on plates prepared by a Manchester firm. He liked them very much, and had been very successful with them. The exposure was quick, but the development exceedingly slow.

Mr. GREEN suggested that a number of negatives might be developed together in glass dishes. They could then be examined rom time to time, so that the whole would be finished in much the same time as one.

The Rev. J. D. RILEY showed an excellent transparency, taken by Mr. Sutton's moist process.

Mr. CASTELLAIN related his experiences in changing very sensitive plates in a Howard's tent. Although the sun faced the window, the plates showed no signs of fogging.

Mr. ELLERBECK said he had worked the wet process with the tent, but if he coated the plate within the tent, the fumes from the ether made it impossible to work without some covering for the eyes. He thought of having glass or talc fitted to the mast, as there was a difficulty in avoiding dust when coating a plate in the open air.

The council was requested to arrange for an excursion.

The meeting was shortly afterwards adjourned.

### Talk in the Studio.

A MAGNIFICENT PHOTOGRAPHIC ESTABLISHMENT.—We learn from *Anthony's Bulletin* that Mr. Kurtz has just erected a new studio in Twenty-third Street, New York, opposite Maddison Park. The outlay connected with the completion of the establishment will cost \$130,000, in round numbers upwards of twenty-five thousand pounds.

PIRACY OF PATENT PROCESSES.—In our advertising columns will be found a caution to pirates, who, we learn, have for some time been guilty of open infringement of the Ferranti-Turner patent process of finishing photographs. Imitation is always one of the annoying risks which high excellence must incur; and so long as unscrupulous people exist, we presume such contemptible forms of dishonesty will be practised; but we would urge upon the attention of all photographers that when they give commissions to those who avowedly seize and practise processes not their own, they practically share in the piracy. There is a compound dishonesty in infringements of this sort. Not only is the invention which some one else has been at the trouble and cost of working out stolen, but advantage is taken of the publicity which the inventor has given to his work—a publicity never secured without cost of personal effort and money. It is the real interest of all photographers to aid in suppressing such infringements.

COMPARATIVE INTENSITY OF ELECTRIC LIGHT AND GAS.—The *Daily News* says:—"Some curious and useful information about the lights displayed from the Clock Tower of the Houses of Parliament is given in a report just made to the House of Commons. It appears that the two semi-lanterns which a spectator at Westminster sees 250 feet above him in the Clock Tower are in the hands of two rivals—one of whom employs gas, and the other electricity, as the source of illuminating power. The Wigham light has three burners, each composed of 108 jets, placed one above another on the same axis. The electric light is produced by an electro-magnetic machine, worked by steam power, the currents being conducted from the machine to the lantern along 1,700 feet of copper wires. The report is decidedly favourable to the electro-magnetic process. Thus Mr. Douglas states that the electric light has a superior intensity of 65 per cent. when one 108 jet burner is used, and of 27 per cent. when three are employed. So, again, as to cost, the electric method produces a saving of 162 per cent., measured in cost per candle per hour, when one 108 jet gas burner, and of 133 per cent. when three jet burners are used."

AMERICAN OBSERVATIONS OF THE TRANSIT OF VENUS.—Mr. R. A. Proctor, writing to the daily papers, says:—"It is already known that the American Government has granted for the purpose a sum (150,000 dols.) nearly twice as great as that which has been demanded by English astronomers from our own Government. America will occupy eight stations, four in the northern and four in the southern hemisphere. At all of these the whole transit will be visible—America being the only nation which has rejected Delisle's method altogether (though England alone now attaches special value to that method, hitherto so unsatisfactory in its results). The idea of occupying Macdonald Island having been abandoned by the authorities at Greenwich, America will join with Germany in establishing stations in that island; and the circumstances which have been regarded at Greenwich as insuperable obstacles to the occupying of the Crozots have not frightened America from the attempt to occupy that post of difficulty and honour. The invitation addressed by Sir George Airy to America to occupy two Delislean stations in the Pacific has not been acceded to."

A CANINE SITTER.—The *Boston Traveller* relates the following dog story:—"G. F. Richardson, of Lowell, owns a magnificent Newfoundland dog. Mrs. Richardson took the children and dog to the photographic saloon to have the group taken; but the dog was in a willful mood, and would not pose, and was turned out. The next day the dog put in an appearance at the saloon and scratched at the door till he was admitted; he then proceeded directly to the spot assigned him the day before, and placed himself in the exact position desired by the artist. The photograph was taken, and when completed put into a box and given to the dog, who carried it directly to his master."

REDUCING WASTE BY GALVANISM.—Mr. E. Bosttcher, secretary of the German Photographic Association in New York, writes to *Anthony's Bulletin* as follows:—"Messrs. Kurtz and Kleihans have obtained at the Patent Office, in Washington, a caveat for precipitating metallic gold and silver out of spent photographic solutions by means of galvanic batteries. This caveat the above gentlemen have turned over to the German Photographic Association, and this association permits every photographer in the land to use such galvanic batteries for the purpose named. Presuming that every photographer knows enough about galvanic batteries to make a long description unnecessary, I would mention that a Smee's battery is the most desirable. It will work for four to eight weeks without interruption; then it may be found necessary to supply a fresh solution of sulphuric acid and to amalgamate the zinc plates. Besides the first cost of about \$5 00, there is no further expense worth mentioning. The whole process is simple and cheap, and does away not only with the noxious sulphuret of potassium itself, but with the royalty attached to its use also."

TO CLEAN BOTTLES.—A correspondent of the *Philadelphia Photographer* says:—"To clean a silver bottle, pour in a strong solution of cyanide; shake a few times, pour out, and rinse with water two or three times, and your bottle is perfectly clean. Keep the solution, and filter and strengthen when required. By doing this you can sun your bath better in two hours than in a week's exposure in the dirty black bottles photographers appear to delight in."

To Correspondents.

A SUBSCRIBER FROM THE FIRST.—By lime water is meant the ordinary lime water which a chemist will supply you under that name, or which you can prepare by placing quicklime in water, which will dissolve a mere trace of the alkali—less than a grain per ounce.

W. W.—The usual strength of Beaufoy's acetic acid is about one-third of the strength of the glacial acid. 2. A brown tone by reflected light on developed collodion prints is not easy to secure. Some approximation to brown may be obtained by toning with a sulphide of ammonium or potassium. A brown tone may also be obtained by the use of Selle's intensifier. 3. Any good bromo-iodized collodion may be used for producing collodion prints. 4. What is meant is a solution of nitrate of silver and citric acid, with the latter in excess. If a solution be made with twenty grains of nitrate of silver and twenty grains of citric acid per ounce, there is often a tendency to deposit citrate of silver; but if thirty grains of citric acid be used, it will generally prevent any precipitate taking place. 5. A ten per cent. solution contains forty-eight grains per ounce. In the formula in question you will add an ounce of nitrate of silver and an ounce of acetic acid to ten ounces of water. 6. If the plates are used fresh, the final application of the gallic acid and chloride solution is not required.

A CONSTANT SUBSCRIBER IN THE COUNTRY.—Our advertising pages will furnish you the best and fullest information.

JOHN STONE.—The precise proportion of water to chloride of gold in a toning bath is not of vital importance. A strong bath works rapidly, and a weak one slowly, and different operators have varied preferences in this respect. Varying from five ounces to ten ounces of water to each grain of chloride of gold may be regarded as convenient average limits. We never recommend carbonate of soda to be used in a toning bath, as it produces a solution which must be used within a few hours of mixing, and a toning bath which will keep is in every way preferable. It is of very little importance whether you use one or two grains of the carbonate, if you use it at all. The solution with two grains will probably become inert sooner than the solution with but one grain.

W. C.—You will require the permission of the authorities of the Inland Revenue department to have a still on your premises; but that permission obtained, you will not have to pay for any license.

G. WILLIAMS.—The defect in question may arise from various causes, but it is chiefly due to the collodion, which is manifestly of the tough, horny kind, yielding a repellent film. Sometimes the addition of a few drops of distilled water to each ounce of the collodion will effect a cure; sometimes the addition of a little of a collodion giving a rotten or powdery film will mend matters. Immersing the plate in the bath before it is as much set as usual is often useful. The plate should rest on pieces of clean blotting-paper, and the inner frames should be frequently washed with clear water. You will find that many articles have been written on the various causes of these matt silver stains in back volumes.

PIERRE REVON.—We do not remember any specific report upon the toxic qualities of pyrogallic acid. Although it is well understood to be a poison, we have no means of verifying the statement that it is as active and virulent a poison as strychnine and similar alkaloids. 2. In the development of wet collodion plates pyrogallic acid may be entirely dispensed with, and in the establishments of many portraitists it has been entirely replaced with iron. In the development of some dry plates, however, pyrogallic acid is at the present time a necessary aid. Even with those dry plates in which a large proportion of ammonia is found valuable in development, some pyrogallic acid is found necessary, and with many dry plates this mode of working does not answer. Almost all the chemicals employed by the photographer are active poisons, some in greater degree than others; and whilst it is desirable to avoid, if possible, the use of the most dangerous, especially those which are injurious when brought into contact with the skin, or which give off poisonous fumes—such as cyanide of potassium—we fear that the possibly dangerous character of pyrogallic acid will scarcely exclude it from the operating room. There is no record, that we know of, of a case of poisoning by pyrogallic acid. We do not know of any proposed antidote, but will endeavour to ascertain if turpentine really counteracts its effects. We hope to have a few remarks on the advantages of collodio-chloride shortly.

CRACKING.—The tendency to crack is partly due to the use of a very highly albumenized paper. To prevent it, be careful not to allow the sheets of albumenized paper to hang until they are bone dry. Before they are absolutely dry, place them one upon another, and cover with a board and a weight. After printing and washing, mount the prints before they are absolutely dry. By these precautions you will prevent cracking, even when there is a great tendency to this defect. A fresh sample of paper will also probably relieve you.

G. L.—Your silver bath is too weak, and apparently you are working with a small quantity in the dish; hence the weak, poor prints, and the irregular, mottled effect. Remember that your bath perpetually requires renewing, as from thirty to forty grains of nitrate of silver are abstracted by each whole sheet of paper sensitized. See article by Herr Kleffel in the present number.

H. J. GODBOLD.—Thanks for sight of the Yokohama Directory. We will forward it as instructed, and will send prints for examination.

N. J. E.—The image is quite out of focus. Either you have not focussed carefully, or you have moved the camera after focussing, or the sitter has moved his head after you have focussed, or your ground glass and sensitive plate are not in precisely the same plane, or the visual and chemical foci of your lens do not correspond. It is impossible for us to say which; you must ascertain which by careful observation of experiments undertaken for the purpose. Try, for instance, focussing carefully some inanimate object that cannot move. If, after careful focussing, the negative is not sharp, next examine carefully to ascertain that the sensitive plate occupies precisely the same position as the ground glass. Take out the lens and measure very carefully the distance of the ground glass from the flange of the lens. Then put a plate of glass in the dark slide, withdraw the shutter, and measure if the distance is precisely the same. If this be correct, try again, and after focussing move the lens slightly in or out as the picture indicates. The lenses of all good makers are, however, as a rule, coincident in chemical and visual foci. 2. As a beginner, you will find it wise to procure, if possible, one good negative as a standard to work to.

M. M.—The chief fault in your vignettes is the use of a background screen much too dark, hence there is no satisfactory gradation into the white of the margin. A very light screen should always be used for vignettes.

P. W. S.—There is no restriction whatever as to the production of cameo vignette pictures. The process is free to every one.

G. D.—Many thanks.

DR. NICOL.—In our next.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR APRIL.

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

Date.	Morning.	Noon.	Night.	Direction of Wind at 9 a.m.	
1	42°	48°	46°	N.N.W.	Rain a.m. and p.m. Very heavy at night.
2	48	48	46	S.W.	Heavy rain a.m. and p.m.
3	44	48	42	S.	A little rain this evening.
4	42	50	44	N.W.	Heavy hail showers this morning.
5	46	50	45	S.	Distant thunder and heavy hail this afternoon.
6	44	51	45	S.W.	Fair all day. Sunny.
7	46	50	42	—	Heavy rain this evening.
8	44	51	46	S.	Fair all day. Gloomy.
9	45	—	43	S.	Heavy rain this morning.
10	47	52	44	S.	Rain at night.
11	46	49	44	S.W.	Rain a.m. and p.m.
12	42	50	39	N.W.	Fair all day. Sunny.
13	38	52	43	N.N.W.	Heavy rain a.m. Sleet.
14	45	50	39	N.	Fair all day. Sunny.
15	44	—	49	S.S.W.	Heavy rain this evening.
16	49	51	49	N.W.	Fair all day. Sunny.
17	49	49	49	S.	Rain p.m.
18	49	50	49	S.	Rain this evening.
19	52	56	51	S.	Rain this morning.
20	54	58	56	S.W.	Fair all day. Sunny.
21	58	60	51	S.	Fair and sunny all day.
22	51	58	51	S.W.	Fair and sunny all day.
23	58	—	53	S.E.	Fair and sunny all day. Rather hazy.
24	54	61	53	S.	Rain a.m.
25	63	69	64	S.	Rain a.m. Very sultry. Distant thunder this evening.
26	68	68	64	S.S.W.	Fair and sunny all day.
27	67	71	64	S.	Fair and sunny all day.
28	63	68	54	S.	Fair and sunny all day.
29	53	60	43	S.S.W.	Fair and sunny all day.
30	53	60	53	W.	Fair and sunny all day.

We arrive at the following from the above data:—

	Mornings.	Noons.	Nights.
Maximum temperature during the month	68°	71°	64°
Minimum ditto ditto ditto	38	48	39
Mean ditto ditto ditto	49.3	55.1	48.7

Number of days on which rain fell ... .. 16  
 Number of days on which no rain fell... .. 14  
 Number of fair days on which it was sunny ... .. 13  
 Number of fair days on which it was gloomy ... .. 1  
 Owing to the unusually warm weather at the end of April, special registrations of the thermometer were taken, exposed to the sun at 12 o'clock on the following days:—

April 25th	94°
" 26th	94
" 27th	103
" 28th	99
" 29th	90
"	Wind from S. and S.W. prevailed.

## The Photographic News, May 15, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

XYLONITE—PROTECTION OF SILVER PRINTS—INFANTS' PORTRAITS—THE SUBSTITUTION PROCESS IN ENAMEL PHOTOGRAPHY—PHOTOGRAPHIC TRANSPARENCIES.

*Xylonite.*—There seems to be no limit to the applications of collodion and castor oil, irrespective of the uses to which photographers put *collodion cuir*. Mixed with zinc white, or other suitable materials, it is applied to as many purposes as ebonite, vulcanite, and other forms of hardened rubber; at the same time the xylonite, or parkesine, as it is commercially called, has this great advantage over caoutchouc preparations, viz., that it is free from the offensive smell of the latter, and possesses, indeed, a camphorated odour, which is really agreeable. We have already noticed the many uses to which parkesine, when prepared of a white opaque nature, is put, being an efficient substitute, in many instances, for ivory, in the case, for instance, of knife handles, pianoforte keys, and the like; but the latest application of all is one more curious still, for it has been found possible to manufacture artificial quill tubes from the plastic material. We are not aware of the proportions of oil and collodion employed, nor what other ingredients are added, but the result is a tough elastic tube, which answers most purposes of the quill, except, possibly, that of a pen. For military and mining fuzes, for camel-hair pencils, and other commercial purposes, these artificial quills appear exceedingly suitable; and when it is borne in mind that the price of the material is but a few shillings per pound, there can be no doubt about a demand for goose and swan's quills made from soluble guncotton. Strange to say, that, notwithstanding the combustible character of its principal constituents, pyroxiline, ether, and alcohol, the material does not burn with greater fierceness than tar, rubber, and such like substances. It would be a famous material for photographer's utensils, and being white, one could always rely upon the same being perfectly clean.

*Protection of Silver Prints.*—There can be no question that the covering of silver prints with a coating of wax or varnish is an excellent method of ensuring their preservation. Let a silver print be washed ever so well, contact at any time with a vitiated atmosphere must always imperil its existence. And this holds good, whether the print is upon albumen, collodion, or any other basis. In a collodio-chloride picture the image is more imbedded in the film than in the case of albumenized paper, and must consequently be more protected from noxious vapours; and where the former have been found to fade and turn yellow, they have most probably been subjected constantly to the air of a gas-lit apartment, or exposed in other contaminated localities. Any surface of metallic silver, if exposed in our dwelling houses continually, soon tarnishes, as we all know, and under these circumstances it is really a matter for astonishment that silver photographs in our libraries, dining rooms, &c., last so long. The bright silvered ornaments worn by officers at a review or field-day are at once tarnished if any firing takes place, the fine particles of silver upon the surface becoming terribly discoloured by the sulphur fumes carried into the air at every discharge of fire-arms; and if the silver is in a frosted condition, the metallic particles lying loosely upon the surface, an immediate cleaning of the ornaments becomes necessary, so seriously are they attacked by the atmosphere. It is true, in a photograph we do not have the silver in its white metallic form, nor is it in a perfectly pure state, but, nevertheless, any trace of sulphurous acid in the atmosphere must exert an injurious action upon a film so thin, and sulphur—or sulphurous acid, rather—is by no means a rare constituent of the air breathed in large towns; most coal and coke contains as much as one per cent. of sulphur, and consequently for every hundred tons of fuel consumed

in our cities one ton of sulphur is liberated in a gaseous form. The waxing of a print and rubbing of its surface, or otherwise protecting it from the air, must, then, it cannot be doubted, have a most important influence upon its durability.

*Infant's Portraits.*—Some pretty portraits of children we have lately seen, taken by an amateur, which deserve to be mentioned. In depicting very young infants, it is indispensable almost to take the mother or nurse also, and the difficulty of securing a satisfactory picture of the two is generally very great. Whether carried in the arms, or on the lap, the child's features are rarely on the same plane as the mother's, and if the head of one is in the centre of the plate, that of the other is not, while both are usually shown full-face. These difficulties were overcome, in the series of pictures we allude to, by throwing the infant over the shoulder, the mother's face being turned in profile towards the baby. Besides being a very natural pose, the face of the little one assumes a quiet, contented mood, and is fully shown, while the person of lesser importance is at any rate well seen, the two heads being differently rendered. So as not to show too much of the back of the adult sitter, the pictures were printed in small vignettes. This hint may be of use to those who are troubled with baby sitters.

*The Substitution Process in Enamel Photography.*—In employing the substitution process in enamel photography, it might be well to consider whether the aid of electricity could not be made use of, as in the electrotype process. There is no difficulty, under ordinary circumstances, of throwing down gold or platinum particles upon the silver image, but others of the precious metal group are not so easy to precipitate. With the aid, however, of a gentle electric current it might be possible to press into the service a wider range of metals, connecting the film covered with the metallic image with one pole of a battery, while the other is immersed in a solution of the metallic salt to be precipitated. Only a very weak current of electricity could be used, no doubt, otherwise the metal would be thrown down in too coarse a condition. A few experiments in this direction would, we think, be well worth trying.

*Photographic Transparencies.*—A silver medal is to be given at Vienna for photographic transparencies this year, such as are adapted for employment in the magic lantern, the subjects of the slides, apparently, being of less importance than the process by which they are produced. It is different, now-a-days, to the time when albumen was the only material that could be made to yield good positive transparencies, for now the same may easily be produced by several methods exclusive of those involving the use of albumen or collodion. There is the carbon process, by means of which the prettiest translucent pictures may be secured, of any desirable tint, by simple immersion of the fixed gelatine print upon glass in any of the aniline dyes. Then there is the Woodburytype process, in which similar photographs may be produced in any quantity as readily as prints upon paper. Finally, there is the powder process, that might be employed for the same purpose. In silver printing, Mr. York and Mr. Feneley have considerably distinguished themselves in this branch of photography, although the method of printing, we have always regretted, has never been so largely cultivated here as in Paris, where the firm of Léon and Lévy supply by far the greater portion of the beautiful transparencies one sees everywhere. To our thinking, a photograph never looks so well, or is seen to such advantage, as in the form of a transparency, either in or out of the stereoscope, and it is much to be deplored, therefore, that in this country so little attention is bestowed on their production. Photographers in this country who desire to compete for this, or indeed any of the Voigtlander medals that are yearly distributed by the Vienna Photographic Society, must bear in mind that, to be qualified candidates, they must

first take up the membership of that society, of which M. Fritz Luckhardt, the well known portraitist, is secretary. The details concerning the medals to be distributed this year by the society were given in these columns a fortnight back.

#### FRENCH CORRESPONDENCE.

THE process of enlarging and retouching invented by M. Lambert, of which I spoke in the *Moniteur de la Photographie*, and to which you referred in a recent number of the PHOTOGRAPHIC NEWS, is a matter which engages the attention of Parisian photographers at the present moment. For two years past they have admired the results obtained by this method, without being able to divine how they were obtained; and if the secret has not been discovered, it was not for want of searching for it. These experiments have, nevertheless, not been unfruitful, but have led to various improvements, such as the employment of opaline glass and retouching upon this material: such processes as MM. Liebert and Depaquis have brought forward. To-day, thanks to the patent taken out by M. Lambert, everybody may, by taking out a license, make use of the process. The list of subscribers is already very numerous, and includes many of the best known photographers in Paris and in the provinces. Among the latter is an English artist, Mr. Mevins, who has purchased the right of working the process at Rennes, where he is established.

In reference to the observations of M. Thierrée upon the silver bath and coagulation of albumen, which I referred to in my last letter, two further communications have reached me. The first is from a very skilful amateur, M. Quiquerez (of Nonamecourt), and the second from a chemist of experience, M. Encausse.

M. Quiquerez remarks, that for a long time past alcohol has been cited for the purpose of coagulating the surface of albumenized paper. But if the alcohol coagulates liquid albumen, it is not the case when the substance is dry. He thinks that a dilute alcohol bath would have a very feeble action upon albumenized paper. The best course would be for manufacturers to supply a satisfactory coagulated paper, for the paper of this description usually sold is of a yellowish tint, and lacks brilliancy. M. Quiquerez thinks that these defects are due to the high temperature which is employed for coagulating the albumen. He sends me some specimens of a very brilliant nature, printed upon paper of this kind, sensitized in a bath of four per cent. strength only, to which six or seven per cent. of nitrate of potash had been added. This bath is always allowed to remain exposed to the light, and does not become discoloured even when non-coagulated and strongly albumenized paper is floated upon it. The excellent clichés which have served for the printing of these impressions were obtained with wet collodion, developed by means of a compound made up of—

Distilled water	...	...	1,000 grammes
Sulphate of iron	...	...	25 "
Sulphate of copper	...	...	10 "

The above is dissolved, and to the solution is added:

Alcohol	...	...	45 cub. cents.
Glacial acetic acid	...	...	25 "
Liquid ammonia	...	...	7 "

This is shaken, allowed to repose for the night, and then filtered. The solution does not keep very long, and yields very fine images, of a density almost always sufficient for printing purposes.

But to return to the question of albumenized paper and silver baths. M. Encausse is altogether opposed to a neutral bath. Having had in his possession prints which had become altogether perished, he instituted a microscopical examination of them, and found portions of the surface denuded of albumen. He believes this to be due to an

imperfect coagulation at the moment when the paper is albumenized, and to assure himself of the fact he made the following experiments. He took a piece of Rive paper, the material of which appeared suitable for photographic purposes, and this he treated with albumen, of which he had three samples. The first was pure albumen which had been chlorised by a mixture of chloride of sodium to the extent of three per cent.; and paper treated with this had a very brilliant surface. The second sample of albumen was mixed with ten per cent. of its weight of distilled water, and, like the first, salted with three per cent. of chloride of sodium; this furnished a more uniform paper, but one of a less brilliant nature. The third preparation was mixed with twenty per cent. by weight of distilled water, and salted in like manner to the others.

By preparing the three samples of paper in this way he desired to test the action of the nitrate of silver upon the different thicknesses of albumen, and he was enabled to determine that, in all three specimens, the albumen was not completely coagulated in baths possessed of the same degree of acidity. The thickness of the albumen upon the paper is insignificant in respect to the solidity of the prints. M. Encausse took crystallized nitrate of silver, which may be said to consist of 635 milligrammes of silver, and 365 milligrammes of nitrogen and oxygen, for every gramme of crystallized nitrate of silver. The silver transformed into chloride is neutral, and, consequently, is without action upon the albumen, and there remain, therefore, the 365 milligrammes of nitrogen and oxygen as active principle for the coagulation of the albumen. M. Encausse prepared a bath composed of—

Distilled water	...	...	100 grammes
Monohydrated nitric acid	...	...	369 milligrammes

He floated, for a period of twenty minutes, several sheets of the three kinds of albumenized paper, which were dried with care, and then washed them in distilled water. The rinsings, treated with nitric acid, revealed the presence of considerable quantities of albumen, proving that imperfect coagulation had taken place. M. Encausse pursued the operation, augmenting, with each experiment, the nitric acid by 365 milligrammes, and he found the quantity of albumen decreased sensibly until he had reached the amount of 3,650 milligrammes of monohydrated nitric acid, which corresponds to ten grammes of crystallized nitrate of silver dissolved in 100 grammes of water. These experiments show, therefore, that non-coagulated albumen easily dissolves in ordinary water, and, therefore, it will be acted upon in the toning and fixing baths. It is true that, after the action of light, the film of metallic silver, wherever present, preserves the surface; but this film cannot be retained nor solidified in those parts where the albumen is not coagulated.

At the last meeting of the French Photographic Society, on the 1st of May, M. Derogy exhibited an apparatus most ingeniously constructed from a design of his own. It is a mirror and heliostat for producing photographic enlargements. The instrument is fitted on a stand, allowing one to give the mirror any incline that may be desired, according to the height of the sun in various seasons of the year. This inclination once fixed, a clock-work movement in connection with the instrument sets it at work from morning till noon, and again from noon till evening, imparting to the mirror the requisite incline, and circular movement necessary. In this way the path of the sun is followed with the utmost regularity, and its rays directed constantly in one direction, so that, with the light afforded, enlargements more clear and on a larger scale may be secured than with the ordinary enlarging apparatus.

The instrument may also be constructed without the clockwork movement; in this case, after the mirror has been properly inclined according to the height of the sun, there remains but the circular movement to be undertaken by hand. To the reflecting apparatus is connected a

camera carrying a condenser, and a lens by means of which the enlargements are obtained.

I have just received from M. Léon Vidal a photo-chromic print, which indicates that immense progress has been made in the application of the process by the eminent founder of the Marseilles Photographie Society. If perfection has not been arrived at, at any rate it is not far off. The image of which I have spoken is the reproduction of a painting by Carl Müller, representing Faust and Marguerite in a snowy landscape; not only are the personages and landscape produced with a truth which the best water colour painting could not surpass, but the marvellous effects of oil painting are also well rendered. With such a result before one's eyes, one cannot but think that photo-chromy will speedily supersede chromo-lithography.

ERNEST LACAN.

## THE PREPARATION OF DIFFRACTION GRATINGS.

BY LORD RAYLEIGH, F.R.S.\*

IN the case of developed plates there is more choice of lights, in consequence of the higher sensitiveness. I have used successfully cloud or skylight reflected horizontally from the zenith by a mirror through a hole of two or three inches diameter in the shutter of a darkened room, the frame being set up in a vertical plane at a few feet distance. The principal objection to this plan is the difficulty of estimating the exposure with proper precision—a difficulty which is more felt than in ordinary photography, as it is convenient to develop a good many copies at once. On a really fine day the image of the sun formed by a condensing-lens of short focus placed in the shutter (as used in diffraction experiments) constitutes a very convenient source of light. As the exposure is only a few seconds, there is no difficulty in dodging isolated clouds, whose progress may be watched from within by examining their image with a coloured glass. When there is any haze, this method is not more satisfactory than the other.

With the more sensitive processes artificial light may be employed. I have done a good many copies by the aid of a moderator-lamp (without the globe) at two feet distance from the frame. An Argand gas-flame would probably be still better.

The printing-frame I employ has a thick plate-glass front, against which the original grating and prepared plate are pressed by screws. These are more under control than the springs generally used in the common printing-frames. When everything is ready, the original is placed on the glass front of the frame with the engraved face upwards, care being taken to exclude all grit by means of a camel's-hair brush. The prepared plate is then placed face downwards on the grating, then a pad to equalize the pressure (I have used one of india-rubber), and on the pad the rigid back of the frame, on which the screws are made to press with a moderate force. When the film is delicate, care should be taken to place it in the proper position at once without sliding.

The two surfaces of the plate-glass front of the printing-frame and the back of the original grating may be cleaned in the ordinary way with a soft cloth or wash-leather; but the engraved face of the grating requires more delicate treatment. If touched at all with a solid (wash-leather), the greatest care should be used. I prefer to wash it, when soiled, with a stream of water from a tap, afterwards flooding it with pure alcohol and setting it up to dry spontaneously. Sometimes I have found nitric acid useful; but I always try to avoid the rubbing contact of a solid. These precautions have been so successful that, after several hundred copies have been taken, the originals have scarcely, if at all, deteriorated.

For the support of the photographic film, it is, no doubt, most satisfactory to use optically worked "parallel" glass.

Ordinary glass would fail, for two reasons. In the first place it would generally be impossible to secure a sufficiently close contact in the printing. But even if this difficulty could be surmounted, the spectrum given by the copy would not bear the magnifying power which it is generally desirable to apply. It is, indeed, evident that the glass support of the grating requires the same precision of workmanship as the object glass of the telescope used in conjunction with it.

Although ordinary glass taken at random is inadmissible, I have done a great number of excellent gratings on selected pieces of patent plate. In order to choose the best, I lay the plates on the table in such a position that the bars of a window or skylight are seen reflected in them. Each bar appears, in general, double, one image corresponding to each surface. By sliding the plate about, while the head is kept still, irregularities are easily detected by the shifting or curvature of the images. From a package of two dozen five-by-four plates, as issued by photographic dealers, three or four often lying together may usually be selected as flat enough for the purpose, or, at any rate, decidedly superior to the remainder. It is worth notice that the object aimed at is *flatness* of the two faces, exact *parallelism* being of much less consequence; for it is evident that the interposition of a truly worked prism of very acute angle would produce no evil result. A glass is therefore not to be rejected merely because the two images of the bar seen reflected in it are decidedly separated. The question is rather whether this separation remains constant as the plate is moved about without rotation. I have never seen a piece of patent plate that could not be at once distinguished from worked glass in the way described; so that the test is abundantly sufficient for the purpose. The more delicate methods by which worked glass is examined would be less practically useful.

Whatever kind of glass be used, if the photographic process be at all complicated, there is considerable economy of labour in preparing comparatively large pieces, to be afterwards cut with the diamond to the required size. A five-by-four, or even a four-and-a-quarter by three-and-a-quarter plate will do very well for four gratings. In the case of worked glass, economy is an object; but when patent plate is used, I should recommend five-by-four glasses, as a margin is convenient. Even when, as in the collodion-chloride process to be presently described, the plate for each grating is prepared separately, it is convenient to perform the preliminary operations of cleaning and albumenizing on larger pieces. The cutting of prepared plates requires a little care. I place them face downwards on a sheet of clean paper, make the diamond cuts on the back, and then, before breaking, remove as much as possible of the glass powder. As it is important to prevent any grit from getting between the film and the engraved face of the original, I usually brush the surface with a large camel's-hair brush kept scrupulously clean.

In the preparation of the plates I have used a considerable variety of methods. The process with gelatine and bichromate of potash, described in my previous papers, has decided advantages; but all my efforts to obtain a mastery of it have been unavailing. Plates prepared to all appearance in precisely the same manner, and even, at the same time, turned out differently, while modifications purposely introduced seemed to be, for the most part, without effect. It required a strong scientific prejudice to hold the uniformity of nature in the face of so much adverse evidence. The uncertainty of this method is provoking, as some of the results are exceedingly good; but I gave up my attempts sooner than I might otherwise have done, in consequence of the discovery of another method by which most of the advantages of the gelatine process—namely, simplicity of manipulation and brilliancy of results—might be attained with much less risk of failure.

It is very possible that a photographer skilled in the employment of gelatine might succeed where I failed. In case any such should wish to make the attempt, I will mention

\* Continued from page 221.

a few points that seemed important. The solution of gelatine should be carefully filtered. For thick liquids containing gelatine, albumen, &c., the best filtering material that I know of is tow. The tow should be cleaned from grease by boiling with soda and subsequent washing, and a small plugget of it pushed with moderate force into the neck of the funnel. Some arrangement must be adopted for keeping the gelatine hot, or the operation will hardly succeed. It is important that the coat of gelatine should be even, for which object the glass must be free from grease, and the plate on which the prepared glasses are put away to set perfectly level. Even then a good deal depends on the manipulation; but this is soon learned. The uniformity of the coat may be tested by the colour when the plate is placed on a sheet of white paper and examined in a weak white light. By candlelight the colour of weak bichromate of potash is scarcely visible. The exposure may be from two to six minutes to the direct rays of the sun. I have not been able to detect any deterioration when the plates were kept a few days in the dark before being used.

(To be continued.)

### HINTS UNDER THE SKYLIGHT.—THE EYES.

BY R. J. CHUTE.\*

UNDER this head I recently made some observations on the general management of the eyes; I now come to the consideration of some special cases that require special treatment.

The first of these is crossed eyes, or eyes that one or both are turned. Generally it is desirable to overcome a difficulty of this kind, so that the deformity may not appear in the picture, and it is not the least of the artist's trials sometimes to accomplish this satisfactorily. Where the eyes are badly twisted, both perhaps being turned in or out, the easiest and most effectual method of overcoming the difficulty is to make a profile, if the face will at all admit of it, being careful to place the eye-rest so that the eye that shows will appear to be in a natural position. In such cases as are illustrated by the annexed figure, where

one eye only appears to be affected, they may be made to appear quite straight and natural. By placing the rest at A, one eye will appear to be looking directly forward, while the other seems to look at B. Now by carrying the rest to C the twisted eye will be brought to D, and the difference between them will be so equalized that oftentimes no fault is perceptible in the picture.

Secondly, serious difficulty is often experienced in photographing eye glasses and spectacles. This has been so general that many artists keep a supply of frames, of various patterns, without glasses, to substitute for those worn by the sitter when required. This is well, and is a much less evil than to produce the eyes blank by reflections in the glasses. But to this there is objection in many cases. If the sitter is used to wearing glasses, his eyes are much more easy and natural with them than without. Some persons can distinguish no object whatever at any distance with the naked eye, hence, when an effort is made to look where nothing can be seen, the eye is wearied, and has a strained, unnatural expression, which affects the whole face. Usually a more successful sitting can be had when the sitter's own glasses can be used, and with few exceptions they may with care be

used with perfect success. Glasses that have a very convex surface are the most difficult, as they gather reflection from so wide an angle. Ordinarily, however, a little manipulation is all that is necessary; and this is brought to bear in so positioning the glasses that all reflections will be avoided. By raising or lowering them, by tipping them forward or back, they may be brought into such position as to give the eye perfectly clear. But it must be remembered that this cannot be done without attention to the surroundings in the studio. If there be a light carpet, light screens, or light walls, their surfaces will be reflected in the glasses, and all efforts to avoid it will be fruitless, except by the removal or covering of the reflecting surfaces. Light from the carpet may be avoided by spreading a dark covering over it in front of the sitter for the occasion; screens and walls may be covered by placing a small dark screen near the sitter. But not the least important item in this connection is what the artist himself may wear. A light coat on his back is mirrored in the glasses, or in the eye even, and yet he wonders where the reflections come from! He who wants his pictures free from reflected lights in the eyes will do well to see that they are not produced by anything his fancy or convenience may induce him to put on. Dark drapery is said to be best for the sitter: it certainly is best for the operator.

Thirdly, weak and squinting eyes are often very perplexing, photographically. The first of these must be turned as much as possible from the light, and if disposed to wink very much, which is generally the case, the sitting must be made very short. A dark screen in front of the sitter is a great relief to weak eyes. In cases of this kind care should be taken, too, to see that the sitter does not fix the eyes on any point until the plate is ready to be exposed. This is a point that I fear is too often overlooked, and the sitter is allowed to "gaze" at some object from the time he takes his seat till the whole operation is through with. There are many matters of this kind that affect the comfort of the sitter, and have more or less influence in determining the degree of success in the sitting. A liberal investment of courtesy, patience, and consideration of the feelings and comfort of those who place themselves in our hands for so personal an interview as sitting for their photograph will pay a good dividend.

### CURIOUS CUSTOMERS.—"THE FAMILY MAN."

BY WILLIAM HEIGHWAY.\*

THE consideration that the "family man" is an extremely useful animal—indeed, I might put it that he is almost an indispensable specimen of the *genus homo*—ought to recon- cile us to the little inconveniences his advent in our gallery invariably puts us to; but, alas! we are such an irritable, discontented, and misanthropic class that we do not see any beauty in the sight of that comfortable and portly personage, accompanied by an anxious and loving progeny who direct his movements and assume the responsibility of his appearance, deportment, and expression.

*Scene the First.*—They enter the reception room to select the style for dear pa's picture. Here each one has his or her idea of the style best calculated to do full justice to pa's peculiar form of beauty. "We must have the chiaroscuro effect, for that is splendid for one whose features are bold and prominent as father's," declares the heir to the domains, a youth who, in virtue of his important position in the family, affects a loud tone and a knowing air. "Oh, pa, you must have some of those sweet vignettes—they are so poetic," urges sweet feminine eighteen, who is suspected of unrequited affection and a broken heart, which has brought out a wealth of poetic feeling in the young lady. Others declare in favour of the three-quarter length standing, while others think that the head and breast is far better; and mamma is of decided opinion that papa's legs are so good that he ought to be taken full length.

\* Continued from page 173.

\* The Photographer's Friend

*Scene Two* finds them all hard at work directing the artist in his labours. "Oh, you know, Mr. Photographer, the only good view of our father's face is quite full"—this is the opinion of the eldest hopeful; but the young lady of the poetic temperament suggests, "Now don't you think the three-quarter face, showing the left side, is over so much more classical?" "Oh, no," says master Reginald, who, being a clerk in a wholesale bookseller's, is therefore thoroughly æsthetic in his tastes. "Oh dear, no! the other side is far better." All the other members of the family train have their peculiar ideas, and as no two agree on any point raised, things look very hilly, and there is music in the air as they grow disputatious. Poor Mr. Artist, who has been trying to bring matters to a focus in a vain endeavour to please everybody, finds that he can make no headway at all until he clears out the disputants—a thing he ought to have done long ago. He makes several views of the head of the family's head, and thus provides argument for a lively

*Third Scene*—the judgment on the proof. In this, all the ingenuity of objection is brought to bear on the pictures shown. One is a little too full face, and another barely enough; yet another would be excellent if the slivet had no shadow on it, while there is not a shadow of doubt that another would be more artistic if there was shading to the "biled rag;" and how nice this one would be, if the necktie were straighter, and what a pity pa's nose looks so crooked in that one. Oh! what a beautiful time one enjoys when four or five individuals of healthy imagination, and not too modest utterance of thought, sit in judgment of our work! What a pleasure it is to hear their caudid opinion of our artistic abilities! I think there is nothing so well calculated to extract from a man's composition any little superfluous self-conceit with which it may be embellished, as listening to criticism on proofs; nor is there a more pious penance for sins of vanity and vain-glory than showing proofs to the loving relations of the family man. Thank heaven! the sitter himself does not trouble the discussion with any views of his own, but leaves the decision to his olive branches, with—"Please yourselves, children, and I am satisfied;" but the worst of it is, that, like the deaf adder, they refuse to be charmed, be you charming as you please—though the chances are about a thousand to one that you are anything but charming under the circumstances. If they do, at last, determine on a selection, they won't like your prints, and then there is another scene. In fact, there is no end of scenes until they are no more scene (I should say seen, but the subject has agitated me so that I hardly know what I write). When you see the family man enter your gallery, summon all your forbearance and tenderness, and lay in a good supply of the Christian virtues; and by all means swallow a soothing powder, or you are lost. Make all snug below and aloft, and look out for dirty weather.

#### MR. HADOW'S METHOD OF RECOVERING WASTE.

MR. JEX BARDWELL gives in *Anthony's Bulletin* a method of recovering silver from waste which was, he states, published by Mr. Hadow ten years ago, and has proved in his (Mr. Bardwell's) hands successful. He says:—

"From the frequency with which inquiries seem to be made respecting the recovery of silver from old baths and waste solutions, it would seem that the methods generally prescribed, simple as they are to anyone in possession of a laboratory, yet present difficulties to amateurs out of the reach of furnaces, and that a simpler method of obtaining reduced silver in a compact, fused form (in which state alone can it be relied on for furnishing pure nitrate) is for such persons still a desideratum. The following method will, it is hoped, put the recovery of silver in a compact and pure state within the reach of all, even in the most ill-furnished position.

"Precipitate old nitrate baths with chloride of sodium in excess, and old hypo baths with sulphide of potassium, or, if this is not at hand, with the yellow solution obtained by

boiling lime and sulphur together for some time in water. The chloride and sulphide of silver thus obtained, after washing and drying, are then to be mixed with two or three times their weight of powdered nitrate of potassium. Select a solid piece of well dried wood of about eight inches cube to half a pound of the above mixture; place a small quantity, say half an ounce, on the upper surface, and thrust in the red-hot end of a burning stick. When deflagration has fairly commenced and a cup-shaped cavity has begun to form, add the remainder of the mixture in small quantities at a time (for fear of its overflowing) by means of a spatula or spoon. If this has been skilfully done, the whole quantity may be added without loss, and after the combustion is completed there will be a deep cavity in the block containing the reduced silver in a spongy form, in the midst of a cake of carbonate and sulphate of potassium and chloride of potassium. The whole is to be scooped out and thrown into water, which dissolves the salt, leaving the silver sponge, which, after drying, is ready for the second operation.

"Mix six parts of saltpetre, two parts of dry and fine sawdust, and one part of flower of sulphur. Take a large iron ladle, put a layer of flux about an inch deep on the bottom, and above this alternate layers of silver and flux, using about two parts of the latter to one of the former; press the whole tightly down. On setting this mixture alight it burns with great heat, and after combustion is over the silver will be found in a single compact button at the bottom of the ladle, and after well washing in water it will be ready for solution in nitric acid. By this method a lump of silver weighing many ounces can be obtained with great ease in a very short space of time."

#### Recent Patents.

WE propose placing before our readers the details of various photographic inventions which have been patented during the last twelve months, the specifications of which, owing to the pressure of current matter at the time, have not appeared in our columns at the time of their publication.

#### SILHOUETTE PORTRAITS.

BY F. R. WINDOW.

THE following method of obtaining silhouettes by photography only received provisional protection:—

"The manner in which I prefer to carry out my invention is as follows:—I light strongly a light coloured background, either from the back like a transparency, or from the front, and I place the subject to be silhouetted in front of this lighted background in a position where little or no light can fall upon it from the front. I then take by photography a picture of this lighted background and of the unlighted subject intervening. By this means I obtain a negative cliché of the subject in the form of a silhouette or outline, and I print from this on photographic paper in the usual manner; or it may be printed by means of photo-lithography on any suitable material."

#### STIPPLED BACKGROUNDS.

BY J. LONG, A. FORSYTH, AND J. R. GRIFFITHS.

THE following method of finishing photographs by printing from a second negative is one of the oldest dodges in photography, and it is not surprising that it was not carried beyond the provisional specification:—

"1st. We print in the ordinary way, by any of the known photographic printing processes on paper, a vignette head, or part, or whole figure.

"2nd. We prepare, on a plate of glass, paper, or any other transparent medium, a stippled surface or 'effect' in any coloured pigment suitable for that effect, and in printing we place it in the frame super-imposed on the print, and then by exposing to light we obtain on the print the design on the glass or other medium, shading those parts not required to have the stippled effect, until the ground is deep enough. We then tone, fix, and wash by any of the known methods of doing so. When the print is mounted, we rub the stippled parts with pumice or other abrading powder, and our effect is obtained."

## THE PHOTOGRAPHIC SOCIETY OF LONDON.

THERE is once more a prospect, or at least a possibility, of harmony in the Photographic Society of London. We pointed out in our last that in the state of disunion, distrust, and antagonism which prevailed, no peace could be anticipated, no confidence could be restored, if a council were elected at a local meeting, under the domination of any clique or party, and that an appeal to the whole body of the members was the only course presenting any hope of an amicable solution of difficulties. Happily, that course was resolved upon at the meeting on Tuesday evening last, when, after an irregular and occasionally stormy discussion, some of the details of which it is desirable should be forgotten, Mr. Hooper's resolution was carried, and the election of a staff of officers by the voice of the whole of the members determined upon.

This desirable end having been gained, it is scarcely important to discuss the arguments *pro* and *con*, nor to notice the stormy episodes in the discussion which preceded the voting. It was certainly strange enough that the chief opposition urged against this course was to the effect that it was not in accordance with the old laws; and this opposition was urged by some of those who have so recently condemned these laws as clumsy, contradictory, and inefficient, and have so strongly urged the fact that the society was the maker and interpreter of its own laws. The arguments now are perfectly sound and good, but they are inapplicable. The society is practically in a state of collapse: it does not at this moment possess a quorum of officers by which any law can be administered. All the old officers except two have, we believe, definitely resigned, and so, we believe, have the whole of the new officers. If the maintenance of law were more important than it is, the society is not in a position, does not possess the means, of carrying out the law. At such a juncture the only course the society can take is to begin *de novo* to take the steps which it would do if it were a new society requiring officers. A section of the society, consisting of the resident London members, might, it is true, proceed to elect a complete new staff of officers; but by what notion of right, by what conception of propriety, they—at most two or three score of persons—could undertake such a course at such a time, without consulting the three hundred members residing in the country, we cannot conceive. Certain it is, that such a course would have led to the alienation of country members, and created an irreparable disunion between two sections of resident members.

In the collapse of all ordinary conditions, in the absence of any executive body having legal powers to administer

the law, in the actual vibration of constitutional change and of laws tottering to their fall, surely no course was so constitutional as an appeal to the whole of the members—to that body for whom and by whom all law is provided, and from whose consent all law must derive its force. A breach of law which involved no appeal to the fountain of law would have been unconstitutional, even if it had a good aim; but in an appeal to the members at large the whole principle of constitutionalism is involved: it is an appeal to that power behind the law which is greater than the law itself. It is, besides this, manifestly a conciliatory measure: it is a measure in which everyone practically says: "Whatever may have been my convictions and my feelings, I at once merge them in the general voice of the society, and I agree to abide by its decision." If concessions are involved in the result, no one can hesitate or feel humiliation in making concessions which the whole body politic has determined are right.

To give effect to a course as clearly without precedent as the circumstances are without parallel, a committee was formed at the suggestion of Mr. Walter Bird—that gentleman, we are happy to note, having been one of the active requisitionists, giving valuable aid now in securing this conciliatory measure. This committee proceeded to organise arrangements whereby the appeal to every member of the society might be promptly made, and his vote secured by post, still maintaining the principle of the ballot. Every member will receive a list of the members of the society, and will be at liberty to vote for one person as president, three persons as vice-presidents, and eighteen as members of council. To aid the judgment of those who may be anxious for such guidance, we believe thirty or forty names will be printed in italics, as being those of gentlemen specially suited for office. But every member will be at liberty to select and vote for any name he may choose, but he must not select more than the given number. We might possibly, without impropriety, have indicated the names of some who, in late emergencies, have striven hard to preserve the peace and secure the well-being of the society; but we will refrain from any suggestion which might influence voting. Those members who are interested in the welfare of the society have doubtless noted the names most worthy of trust, and we may add that, although the late council felt it necessary to retire from the position of distrust in which the antagonism of a party action had placed them, there are many illustrious and valuable names which, by a vote of the members at large, might without doubt be again secured to give efficiency and impart strength to its new legislative body. We would only, in conclusion, urge upon all members of the society to send in their lists of names without delay, so that not a vote may be lost.

## PHOTOGRAPHY AT THE INTERNATIONAL EXHIBITION.

THE display of photographs at the International Exhibition at South Kensington is a great improvement in every way upon those of several preceding years. The gallery in which the contributions are hung is convenient, accessible, and well lighted; and the pictures, consequently, receive full justice. The room apportioned this year to photographs is the first to the left on entering the vestibule of the Albert Hall from the Conservatory, and is technically described as the Crush Room of the Hall. The photographs are hung on the walls and upon a series of screens, the arrangement throughout being, so far as we can see, good and satisfactory. Several of the contributions have been exhibited before at the exhibition of the Photographic Society, but they possess sufficient interest and excellence to be well worthy of this larger and more prolonged publicity.

It is noteworthy that the exhibitors of portrait and figure subjects, and of reproductions, are relatively much

larger here than at the regular photographic exhibitions. The visitor cannot but be struck with the high quality of the portraiture generally; and the close juxtaposition of English and Continental examples permits a ready comparison as to the relative excellence of the two which is interesting, and will probably be found instructive. An impression prevails in the minds of a large section of the cultivated public to the effect that Continental photographers—or, at least, Continental photographs—are in advance of those of this country; and the common explanation in the popular mind is to the effect that “the light is better” on the Continent, the illustration being thus afforded, with amusing persistence, of the common notion that excellence in photography is more due to material conditions than to personal skill and culture in the photographer. In the gallery at South Kensington there is ample evidence, for those who compare intelligently, to prove that English photographs are fully abreast in excellence of the best Continental work. With equal merit in result, there is this essential distinction between the two: the Continental work is more elaborately and skilfully retouched; but the best English work, with equal or superior artistic qualities, is more natural and less sophisticated. Without entering into the proverbial odiousness of comparison, we may fairly point, in illustration of our position, to the magnificent work of Adele, of Vienna, and Bergamasco, of St. Petersburg, and compare them with the large work of Mr. Valentine Blanchard and the smaller work of Mr. Faulkner. The contributions of the Continental artists are exquisitely beautiful: generally very charming models, well posed, well lighted, and well manipulated; but subsequently worked upon, both in negative and print, with the minute care used in ivory miniatures, even where the pictures are of life size. Those of Mr. Blanchard, on the other hand, with a few skilful touches, to which they owe only freedom from technical defect, rather than elaborated finish, are excellent in virtue of admirable lighting, fine pose, and life-like character expression, the result of suitable lighting, pose, and a masterly general treatment. There is a degree of power and artistic quality which is, to a great extent, worked out of the Continental examples by over minute finish. The comparison of Faulkner's portraits of children is in no less a degree conclusive in favour of England. Nothing more perfect can be conceived, in every quality which constitutes good portrait art, than the gems which Mr. Faulkner exhibits, comprising some old ones and many new ones. Baby life, in its most beautiful and winning phases, has been seized and photographed with a technical and artistic excellence rarely accorded to adult sitters.

Another interesting phase of this exhibition is the presence of many singularly fine figure studies, the work of amateurs. Mr. Crawshaw's work is well known, and he sends here some of his finest and most charming. Mr. Cecil Wray, another amateur, contributes two or three rare gems in portrait and figure studies. The “Little Fruit-Seller” (4346) is the figure of a pretty little unkempt, untended looking child, tapping at a door in hopes to sell some fruit; the clever composition, the skilful use of a weak direct sunlight giving an effective cast shadow of the child, and the feeling and tenderness generally thrown into the picture, indicate art skill of no common order. A profile portrait study, and another a full length one, with the interior of a conservatory as background, are also very fine. Two pictures of childhood, by Miss E. Morris Mason, are also among the amateur triumphs in figure photography at the exhibition which are well worthy of attention.

Proceeding to notice contributions in *genre*, we find amongst the most striking contributions the noble composition of Messrs. Robinson and Cherrill, “Preparing Spring Flowers for Market,” which, being here well hung and fairly lighted, appears to still greater advantage than it did in the Photographic Exhibition.

We have already very fully expressed our high appreciation of this picture, and can simply add that fuller examination increases our admiration. The charming “Passing Stranger,” the “Gleaner,” and a life-size figure study, are sent by the same firm. With this class of work we do not find here, nor have we ever seen out of England, anything which compared with the pictorial photography produced in England. Mr. Bruce, of Dunse, sends several works of very great merit of the same pictorial class. His “Work,” “Glossy Leaves,” “Wanderers,” and “My Mother,” are here. All are admirably conceived, and capably rendered. “The Wanderers in a Foreign Land” is perfect. Mr. Earl has some capital examples in the same line; but his most novel work consists in some portraits of dead wild fowl of the most marvellous excellence. We have wild duck, mallard, curlew, and Guinea fowl, the size of life, or nearly, rendered with a degree of perfection that seems almost incredible. The perfect modelling and admirable general rendering are matters of course to a good photographer; but the minute renderings of texture, and the minutest nuances of tint and shading in the plumage, are rare and almost unexpected perfections. In our next we shall conclude by a notice of landscapes and portraiture generally.

#### LANDSCAPE PHOTOGRAPHY: ITS PLEASURES AND PROFIT.

BY W. NEILSON.\*

I HAVE been requested to read a paper connected with landscape photography as suited to the present season, when we are about to make engagements for out-door meetings. The design is merely to make a few general remarks, with the idea of calling up some foretaste of the pleasure and advantage to be derived from such meetings, in the hope of inciting our amateurs especially to bring us proofs that they are successfully prosecuting that work which particularly belongs to them, and in which they have already shown so much excellence. I do so trusting that the members will supplement what I say with practical suggestions, knowing that many of them are better qualified for that than I am.

As introductory, I shall make some remarks on the position of photography. It sounds something like a truism to say, now-a-days, that photography is “a great fact;” but it may be doubted whether the import of the fact has been duly realized by the general community. The word “photography” is apt merely to suggest the results of certain processes which fill albums and portfolios with transcripts of every variety of face and place on which the sun deigns to shine. When we consider that almost every civilized being has at least one such album, or, at any rate, that there are as many albums as civilized beings in circulation, the idea is, indeed, stupendous; indicating, as it does, a universal process that may almost be said to have covered the world with pictures. But the word “photography” is suggestive of much more than the pleasure to be derived from albums and portfolios, which are in themselves vouchers of an immense producing agency. In short, photography, by creating a trade of anything but despicable proportions, has become a partner in the commercial world, adding something to those international bonds that draw mankind together.

A complete view of the subject would be interesting in many ways. But at present just consider, in passing, the thousands of operators it has called into being—I do not call them artists, for they are not necessarily so, although we have names among us that will stand second to none in any school of the day—the thousands of assistants, the thousands of printers, the thousands of spotters and retouchers, the thousands employed in producing paper, the thousands employed in providing chemicals, and the thousands who retail them; to which may be

\* Read before the Edinburgh Photographic Society.

added the benefits incidental to Her Majesty's Post Office, and a variety of water companies, and even (to descend to an albumenized point of view) the encouragement given to the breeding of hens—I say, when you consider the sum of all these varied and extensive results of the art we practise, the import of the word “photography” is vastly increased. Then, apart from its special art, and the trade it has originated, its services to science are becoming noticeable. We have already seen the astronomer call in its aid to help him in solving his difficulty of the solar eclipse, and again he is about to rely greatly on it in dealing with the transit of Venus. Important as these services are in themselves, they may be received as intimations of possibly greater services yet to be rendered in the unknown future. But whilst photography reaches sun, moon, and stars as a servitor of science, it is also a mighty servitor of our common humanity.

I presume we have all felt, in reading a memoir or perusing a volume of travels, that the interest is intensified by having a likeness of the individual, or exact illustrations of the scenes described. In fact, a memoir without a likeness, unless written by a very able hand, is apt to give merely some prominent incidents and sectional views which do not convey a completeness of character. But add a likeness, and it serves as an index to the man, and the vague and fragmentary shape, and we arrive at a truer interpretation of his character. This illustrating of books is a wide and useful field in which photography promises to play a conspicuous part, for I believe most people would prefer a photographic likeness in a memoir to any other—of course, I mean a good photograph, that has not been beautified, let us say, with retouching. And, in connection with this style of illustrating, the public are indebted to photography for the likenesses it has scattered over the land of the great and good men of the day. However we may admire the heroic characters and standard-bearers of the day, we feel as if we knew them better when we have their likenesses in our albums. Through his countenance we read the man, enter into his character, and are more drawn towards him with that touch that “makes the whole world kin.”

Is it too much to say that the national patriotism is enhanced by having the likeness of the royal family, who represent our national greatness, made so familiar to us? I think not. It is not always the most powerful influence of which we are most conscious; and our characters may be moulded by an unrecognized agency. Suppose a man has a picture gallery, filled with bestial countenances and loathsome expressions: will he by habitually looking at them feel himself elevated and refined? But it would be very different if the heads were expressive of all that is noble and good. Whilst consciously admiring them, he would, however unconsciously, become influenced by the qualities they expressed. The noble things, through his admiration, would leave a mark on him. This is a chief principle by which art becomes a benefactor of society. I have stated it thus to illustrate what I mean by saying that photography, by issuing broadcast likenesses of the good and great, confers a blessing on the country.

Then there is what may be called a moral aspect of photography, in so far as it helps to perpetuate the home influences, by presenting the home faces. When one's memory for words is defective he has recourse to a memorandum book. In like manner the album serves the defective memory for faces. If we could remember our friends' faces as distinctly as when they are present, there would be little recourse to the photographic memorandum book, except as to a curiosity. As it is, the carte album has its mission. Let us take one case, of thousands of such, as a sample. When a young man goes (say) to India, “out of sight” is apt very much to become “out of mind.” He finds himself in a new position among new acquaintances, which open up temptations to extravagance and dissipation, and for-

getfulness of the wholesome restraints of his old home. In such circumstances, what an advantage it would be for him to open his album every night and look over his mother's face and the rest of the family, and the scenes of his earlier days! His household goods would still be with him, restraining him with the old home influences. And, take note, there is one pretty carte which he looks and looks at, and actually kisses, at the risk of producing a yellow stain. Well, what a wretched being he would be without that piece of paste-board! In conclusion of this subject, just think of all these albums confer on millions of people! Not a carte among them but calls up a happy smile in some face, and a blessed throb in some heart.

These results of photography to which I have alluded are interesting from their variety, and imposing from their magnitude. But to the photographer they should be something more; for he can think of them as the great work in which he also is engaged. A man's character is partly moulded by the nature of his work; or at least, by the ideas he has regarding it, “like the dyer's hands, subdued to what it works in;” and if the photographer, instead of looking upon himself as a man whose function is to develop plates at so much a head, could habitually think of himself as a component part of the great whole that is producing such important results in the world, he would induce a habit of higher self-respect that might tend to make him both a better photographer and a better man.

We now come to consider the last branch of the subject—out-door work; of which I am here bound to say, “though last, not least,” although I am going to commend it on no higher a principle than that on which we turn horses out to grass. Nature, always provident for the needs of man, has provided two things in especial abundance, which is equivalent to an intimation that these are especially required—cold water and fresh air. It is to be hoped photographers have enough of one of these in the dark-room, though it is greatly to be feared that they have a plentiful lack of the other; consequently they must seek it elsewhere. There is another ample provision of nature from which mankind have taken a hint: the earth, which, in order to be properly productive, requires at times to be fallowed. Men whose brains are much employed, and some of whom that cannot be said, have wisely taken this as a precedent periodically to quit their habitual work and let themselves be fallowed. They accomplish this in varied ways: chiefly by fishing and shooting. Fishing is no doubt a delightful employment for those who like it; but even if one uses the fly, getting quit of the difficulty of putting the worm tenderly on the hook, “as if you loved it,” according to Old Isaac, he is very much tied down to one low-lying locality. Following the grouse on the hills is certainly an airy and healthy employment for those who require that sort of excitement. But there is something more excellent than rod or gun—the camera; with that on our shoulder we can face the smile of mother Nature, feeling that we have no mark of blood upon us.

(To be continued.)

## Correspondence.

### ANENT RECOMMENDATION WITHOUT TRIAL.

SIR,—Mr. Martin has again appeared, and honoured me with a rather lengthy epistle. I think, however, my former letter was sufficiently condemnatory of his proposed gas bags, and that your readers will thank me if I decline to go over the ground again. On two points, however, I must put Mr. Martin right. First, he seems to think that his first letter caused me to “feel sore.” I have rubbed far too long against angularities to feel sore at anything; and were I ever so thin-skinned, I am sure that there is nothing in his letter could give me a thought except the desire to prevent his setting any o

your simpler readers wrong. And, secondly, my friend Mr. A' is not, as he seems to think, an amateur, but a practical as well as thoroughly theoretical mechanic of over a quarter of a century's experience.

The real fault I find with Mr. Martin is, that he recommends the adoption of notions that he has not tried, and which, although their uselessness may be patent to many, are yet likely to mislead those who know no better. We have a good example of this in his article in the *News* of April 17th, page 190, where he gravely recommends his readers to insert a sheet of blue glass between two sheets of yellow in the window of the dark room. Mr. Martin must know that a yellow glass is yellow simply because it transmits the red and green rays, but intercepts the violet; and that a blue glass is blue because it transmits the violet, and refuses to pass the red and green. If he knows this, and will give the matter one minute's consideration, he will see that the effect of his recommendation will be to produce darkness just in proportion to the purity and density of his colours. The most satisfactory way to select a suitable colour for the window of the operating room is to examine the glass with a prism, discarding any sample that allows a trace of blue, and using only that which passes the red and green. This will generally be found to be a fine orange, which may be used with perfect confidence, anything else leading only to vexation of spirit.

On one other point, perhaps, I had better put Mr. Martin right. He says, in reference to the letter of "Oxygen," that a pint of water weighs only a pound, and that 112 pounds will be fourteen gallons. If, however, he will take his pencil, or do a little mental arithmetic, he will find a pint to weigh just one-fourth more, and the 112 pounds to measure just one-fifth less.

There! I've done with fault-finding, and beg to shake hands in spirit with Mr. Martin, who, I'm sure, is a first-rate fellow, equally anxious with myself to do all he can for the benefit of our much-loved art, and equally ready to give and take a little brushing when it is required.

Edinburgh, 2nd May.

JOHN NICOL, PH.D.

#### ELIMINATING HYPOSULPHITES, AND PRECIPITATING SILVER AND GOLD.

SIR,—I have noticed, on several occasions during the past few months, that there have been several extracts in the *News* from American journals, purporting to be new discoveries on the above subjects by American experimentalists, which are, in reality, due to Englishmen—*e. g.*, the elimination of hyposulphites. Amongst these there is mentioned the hypochlorites. In this case it is well known to the older photographers, and those who are constantly using the preparation of hypochlorite of soda introduced by me for that purpose, that what credit or otherwise there may be attached thereto belongs to England.

More recently, these compounds have been re-discovered by them to precipitate the silver from hypo fixings. This was demonstrated by me, at the meetings of the societies in London, many years since, to show their action on the compound hyposulphites of soda and silver. Knowing this from the first, I recommended a solution of ammonia as an after bath, to render any possible trace of chloride of silver thus precipitated—in the prints under treatment—soluble, and so easily washed away.

Again, our cousin on the other side of the Atlantic, in a great fit of generosity, makes a present to the photographic brotherhood of the method of reducing the silver and gold from fixing solutions by a Smea's battery. It is well to remember that this English device is freely given, that photographers may be free from the penalty of precipitating by liver of sulphur, which appears to be protected by patent. I think that I may claim to be the first who brought this matter before the photographic public, and made a compact apparatus with filter combined.

As one who has never protected in any way the devices brought to the knowledge of photographers, I make this reclamation for English photography.—Yours, &c.,

8, Kingsland Green, May 13th.

F. W. HART.

[Photographers generally, especially all familiar with reports of South London meetings, where Mr. Hart has frequently demonstrated, will recognize the justice of these claims.—ED.]

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF LONDON.

THE usual monthly meeting of this society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, May 12th, Mr. J. SPILLER in the chair. Dr. MANN, acting as secretary, read the minutes of a preceding meeting, which were confirmed.

Mr. PRITCHARD read an interesting communication from Herr Obernetter on his method of reproducing negatives by means of the powder process, and exhibited a number of reproduced negatives which, as the chairman remarked, were indistinguishable from the originals.

Mr. WOODBURY also showed some remarkably perfect results in negatives reproduced by a similar method, substituting gum for dextrine, and glucose for cane sugar. He found that a negative reproduced thus in graphite was really more vigorous in printing than it seemed, and must be kept apparently thin, in order to print in like manner to the silver negative.

After a vote of thanks to Mr. Pritchard, Mr. Davis took the chair, and

Mr. SPILLER read a note on some experiments with coloured bromide films, undertaken to test Dr. Vogel's theory as to a film being made sensitive to non-actinic rays by saturating with a colour which absorbed those rays. His experience did not confirm that of Dr. Vogel.

Mr. STILLMAN had undertaken a series of experiments in the same direction, at the request of Mr. Lockyer. In all cases he found that the presence of colour retarded rather than accelerated. He had tried all kinds of dry plates, including some of Col. Wortley's, which were very sensitive; but he obtained no results with colours which exceeded those obtained with the bromide alone. The exposure was much increased by colour, sometimes no impression at all being obtained after an exposure of two hours. He had come to the conclusion that Dr. Vogel was mistaken in supposing that any increased sensitiveness was due to any physical cause. He believed that increase of sensitiveness must be looked for in chemical causes, such substances as the carbonate of silver and fluoride of silver presenting some promise. The latter presented a difficulty in its insolubility, so that he had not been able to get sufficient into a film to be of service.

Col. STUART WORTLEY had found a similar difficulty in regard to the fluoride of silver. In his experience with Dr. Vogel's method he had met with some success. He had found that by the use of other nitrates—notably the nitrate of nickel—considerable advantage was obtained. He had also been trying various experiments with the addition of organic substances to emulsions—salicine, for instance. Allusions had been made to Mr. Carey Lea's suggestion as to the use of this substance. He thought that gentleman could not have been reading the English journals for some time past, or he would not have proposed this as a novelty, as it had been applied so long ago, both by himself and Mr. Henry Cooper, in connection with the bromide emulsion process. It was curious that salicine in connection with sulphuric acid struck a deep crimson colour, which had a remarkable effect on the sensitiveness. The subject was a very fruitful one for experiment.

Mr. DAVIS believed that a large field was still open to investigation, as to the value of various silver salts, which had, of late years, been comparatively neglected.

Mr. G. HOOPER then read a paper on the collodio-chloride of silver process, and exhibited various examples, some of which had been in existence nine or ten years without change.

The CHAIRMAN (Mr. Spiller), in inviting discussion, said the question of permanency having been raised, he had examined some he received from Mr. Bruce two or three years ago, and found no sign of change.

Mr. SAWYER had but very slight experience with the process; but some transparencies he once produced by it had faded, possibly from want of care in producing them. He did not see any advantage over albumen. If permanency were desired, why not try the carbon, about which there could be no doubt?

Mr. PRITCHARD had produced some transparencies by the collodion process two years ago, and there was certainly no change in them; they were as perfect as when they were produced.

Mr. BLANCHARD was a short time ago looking over a drawer of old prints by Mr. Faulkner, who used the collodio-chloride process some years ago. He had found commercial difficulties in carrying it out, but, so far as permanency was concerned, both

Mr. Faulkner and himself could in every instance pick out the collodio-ehloride prints by their freshness and purity, whilst all the albumenized prints had lost their first bloom.

The CHAIRMAN, after a few further words on the subject, announced that at the June meeting Mr. Keene would read a paper on the use of gelatine as a vehicle for silver salts; Mr. Kennett would read a paper on the gelatine emulsion process, with demonstration; and Col. Wortley would read a paper on development. The ordinary meeting would be now adjourned, as they would commence

#### THE SPECIAL MEETING.

The CHAIRMAN, in opening, referred to the proceedings of the last meeting, and his promise to call this special meeting. He had endeavoured to get a council meeting, but only six gentlemen attended, and he regretted to say that he had had definite resignations from many members of the council: Mr. Crawshaw, Professor Stokes, Sir Charles Wheatstone, Captain Abuey, and Mr. Spener, had written and resigned; Mr. Glisher, Mr. Robinson, Mr. Bedford, Lord Lindsay, Mr. White had also gone. There only remained of the old council: Mr. Mayland, Mr. Wharton Simpson, Mr. Dallmeyer, and Mr. England.

These gentlemen all reminded the chairman that they had definitely resigned.

The CHAIRMAN resumed, that in that case there were but Mr. Blanchard and Mr. Davis.

Mr. DAVIS explained that as treasurer it would be inconvenient for him to resign until another treasurer were properly appointed; but he had no intention of retaining office unless elected by the voice of the society at large.

The CHAIRMAN said he had on his own responsibility asked Mr. Fox Talbot to act as president, but that gentleman had declined.

Mr. HUGHES then proposed the first portion of the resolution announced in our last, modifying the 7th rule, which was passed in February. The modification was to give power to a special meeting to fill vacancies in the council.

Mr. STILLMAN seconded the resolution.

Col. WORTLEY proposed, as amendment, that the special meeting for such purpose should be held within a month of the occurrence of vacancies, or, in the case of vacation, immediately on the resumption of meetings.

After some conversation on points of detail as to the number of vacancies which would justify a special meeting, in which Mr. Davis, Dr. Mann, Mr. Howard, Mr. Hughes, Mr. Stillman, and Mr. Sawyer took part,

Major MALCOLM said they had heard from the chairman of the loss of various great and valued names—names which certainly, so far as he was concerned, had formed one motive for his joining the society. This loss was the result of certain resolutions they passed in February by a majority of three—resolutions which it was clear the society at large did not endorse. He had proposed that these resolutions should not be confirmed, but his suggestion was not heeded. Now he found them engaged in altering these very resolutions; and he could not but think their best plan would be to rescind them altogether. The chief danger which, it seemed to him, the society had to guard against, was small majorities carrying vital changes by surprise.

Mr. BLANCHARD thought that the old law, which left the filling-up of vacancies in the hands of the council, was much better. He had not wished to act precipitately, but he now tendered his resignation.

After some further irregular conversation,

Mr. HOOPER said nothing could more forcibly illustrate the folly of unconsidered and piecemeal legislation than the fact that, within a couple of months of passing resolutions which had destroyed the peace of the society, they found it necessary to alter these very laws. He had given due notice of an amendment, which he would move when the second part of the motion came on.

After some further conversation, the first part of the alteration of Rule VII. was passed, incorporating Col. Wortley's amendment.

Mr. GOSLETT begged to tender his resignation as a member of council.

Mr. SPILLER felt in the same position; he only held office until a new council could be constituted.

Mr. HOWARD tendered his resignation.

The CHAIRMAN said he had received a notice of motion from Mr. Hooper, but not in time to send out to members.

The second part of the motion for altering Rule VII. and filling up vacancies having been moved and seconded,

Mr. HOOPER moved his amendment, which was printed in our last, the effect being, that in the present crisis of the society, no

legally constituted executive existing, an appeal to the whole of the members to appoint a new council was the only mode of restoring the society to harmonious working.

Col. WORTLEY said that the resolution was in opposition to the laws, and the chairman should rule it out of order. Further, he objected because he had received no notice.

Mr. STILLMAN said the motion was in opposition to the resolution just passed, and a deliberative assembly did not pass resolutions in one half of a meeting which opposed resolutions passed in the other half.

A confused and angry interjectional discussion followed, in which it was asserted that Mr. Hooper's project would be impossible as well as illegal.

Mr. HART sympathised with the intention of the resolution, but thought that an alteration of the law should be first secured.

Major MALCOLM seconded Mr. Hooper's resolution. He saw no difficulty in working it. It was, in fact, the plan adopted in another society with which he was connected, and there it worked easily and well. Possibly, in sending round a complete list of names to country members, it might be well to indicate in some way a list of thirty or forty of the most eligible men. He felt this consideration of thus consulting them in forming a council was due to country members. He was one; he was not in the trade; he had only very recently joined the society, compounding or his life membership by a payment of eleven guineas; he felt entitled to speak on behalf of country members. He would only make one more suggestion: he hoped that some guarantee could be given, if they once more got a good council, that it should be fairly treated in future.

Mr. HUGHES said that such an appeal to country members was not in accordance with law. They had no power to do it. They must first alter the laws, and give due notice to all the members. The members generally had no notice of this change. The requisitionists were pretty sharply reminded of the necessity of detailed notice before, and he saw no reason for not applying the same law now.

Mr. MAYLAND was delighted to see so much respect for the law so suddenly displayed, but thought it was sadly out of place as applied now. He most strongly supported Mr. Hooper's motion as being at this juncture the only mode whereby peace, unanimity, and confidence could be restored to the society.

Mr. HOOPER admitted that there was no provision by law for his motion; but he held that as they had now no executive, and must begin *de novo* with something, this was the proper way to begin.

The CHAIRMAN attached much importance to Mr. Hooper's resolution. Admit that it was not in accordance with any law: if the whole society agreed to ignore the law, there could be no one to call them to account.

Major MALCOLM pointed out that the objection of Mr. Hughes, that no notice had been given, fell to the ground. Mr. Hooper had given notice, but there was no efficient executive to give it to members.

After further desultory discussion, in which Mr. Hooper, Major Malcolm, Mr. Hughes, Mr. Davis, and others took part,

Mr. STILLMAN proposed that ballot papers be sent to all the members.

Mr. HOOPER said that was just the principle of his resolution, which Mr. Stillman had denounced as illegal.

Mr. HUGHES asked if the meeting intended to carry out the laws?

Mr. EDWARDS asked if voting by balloting papers were not a part of the new laws passed in February?

Dr. MANN said no; that was proposed in the draft laws.

Mr. WALTER BIRD said that the proposal, although not in accordance with the provisions of law, might, under existing circumstances, be the wisest course to restore confidence. If he thought that the gentlemen of the old council, whom they esteemed highly, would stand for election by the votes of the whole society, he would support Mr. Hooper's amendment.

The CHAIRMAN then asked the members of the old council present whether they would stand in the event of their election under Mr. Hooper's plan? He asked seriatim the question of the following gentlemen: Mr. Wharton Simpson, Mr. Mayland, Mr. Davis, Mr. Blanchard, Mr. Dallmeyer, Mr. England, and Mr. Pritchard. Each gentleman said that in the event of his election by the voice of the members generally, he would accept the duty with pleasure.

The CHAIRMAN then put Mr. Hooper's amendment, which was carried by a large majority, seventeen voting in favour of it, and eight against it.

Mr. BIRD then proposed that a committee be appointed to give effect to Mr. Hooper's proposition; and a committee consisting of the following gentlemen was appointed: Messrs. Hooper, Bird, Blanchard, Hart, Sebastian Davis, and Major Malcolm.

The meeting was then adjourned until Tuesday next, and after a vote of thanks to the chairman, the proceedings terminated.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of this society was held in the Hall, 5, St. Andrew Square, the president, Mr. R. G. MUIR, being in the chair.

The minutes of previous meetings were read and approved, and the following gentlemen were admitted ordinary members: Dr. David Murray, Messrs. Robert Smart and William Cunning.

Mr. WILLIAM NEILSON then read a paper entitled, "Landscape Photography: its Pleasures and Profit" (see page 235). At the conclusion of the paper Mr. Neilson said that he had amused himself by making some approximate calculations of the quantities of some of the material consumed by photographers. As, however, his paper had taken up so much time, he would not trouble the members at present with the results. He would just mention one item which he thought was very suggestive, and it was this: that in addition to what they might consume at the breakfast-table, photographers throughout the country use about one million of eggs per annum in the various processes into which albumen enters. He also said that before sitting down he might call the attention of the meeting to two of the very beautiful autotype enlargements which were hung on the wall, as they formed capital illustrations of his remarks on the importance of suitable foregrounds. The one was a very fine photograph of the Trossachs, with Ben Venno in the distance; or, rather, it ought to be in the distance, but in consequence of the want of a suitable foreground, the smaller hill with the trees seemed to be really a part of the larger mountain, the composition being altogether faulty, and the effect unnatural. The other, a view of Loch Katrine, although not better as a photograph, was really a grand picture, and gave a true conception of the view. If, however, the members would cut off the foreground, the charm, and grandeur, and natural effect would be lost, as the idea of distance was altogether absent.

Mr. ROSS said that he was probably one of the very earliest landscape photographers, and he could assure all present that there was a charm in the practice which only landscape photographers knew. He could endorse every word Mr. Neilson had said of its pleasures. It had, no doubt, its drawbacks, as everything else had; but none that with care, judgment, and patience might not be overcome. The painter could select the point of view that pleased him best, and if the foreground was not to his liking he could select one more suitable and put it in; but no such good fortune fell to the photographer: he has to move from point to point till he gets what is required, and if his soul was in his work he did not grudge to travel many a long mile to secure his object. His own habit had been to devote the misty days to such prospecting, and even that was glorious work, as the fine old hills of our native land never looked so grand as when seen glimpse after glimpse through masses of rolling mist. Those who determined to make good landscapes must not expect to be able at all times to do so, but must patiently wait for suitable atmospheric conditions. The work of several of our popular landscapists is very justly admired, but few of us know how long they have sometimes to wait before they get what they want. Probably one of the most popular pictures in the market is that of one of our Highland bridges, and if patience in its production be an element of popularity, it well deserves it, as the photographer actually waited in the vicinity for six weeks before he was satisfied with the conditions under which the negative was taken. He was glad to say that landscape negatives had not as yet been to any extent subjected to the abomination of retouching, and he hoped they never would. The truth, and nothing but the truth, should be the motto of every landscape worker, and he should look upon every proposal to bring the landscape under the retoucher's hand as a charge against the Divine Architect of having done His work imperfectly.

Mr. PANTON then stated that the president and he had the previous week made a short tour with their cameras, and gone as far north as the Clachan of Aberfoyle. The result of the

trip had been some fairly good negatives, prints of which he laid on the table for inspection.

After the prints had been examined,

Dr. DICKSON said he thought Mr. Panton had hardly done justice to himself and the president in speaking of the negatives as "fairly good." They were, he thought, specimens of very high class landscape work, and showed not only that the dry plates used were faultless, but also that he (Mr. Panton) knew how to use them to produce the very best effects; and he (Dr. Dickson) would like to know what process Mr. Panton had been working.

Mr. PANTON replied that it was one that the dry workers of this society generally liked very much; it had been introduced by the vice-president some years since, and was well known as Davies's "beer and albumen."

The adjourned discussion on preserved sensitized paper was then resumed.

Mr. TURNBULL stated that since he had introduced the subject he had continued his experiments, and found that the strength of the citric acid solution then recommended was not sufficient to keep the paper for any great length of time, but that if it was increased to fifteen or twenty grains per ounce he thought it would keep indefinitely.

A letter was then read from Mr. PEAT, of London, in which he said that he had got some of Durand's paper in 1872; that it had been forgotten till December, 1873, when it was found quite brown. He had, however, printed some pieces, of it then, and three months after they were put into the toning bath, when, to his surprise, the discolouration altogether disappeared, and they turned out good prints, with "fine creamy skies and white high lights." Some of the prints were exhibited, and seemed fairly good, and not unlike results from recently sensitized paper.

Dr. JOHN NICOL said that he had intended to make an examination of some of the samples of sensitized paper, but had only got a commencement made of his experiments that afternoon. The samples showed that they all contained an excess of acid, and he hoped by next meeting to be able to report both as to the kind and quantity of acid in each sheet, and also whether the acid had been mixed with the silver in the bath, or in a separate solution, as used by Mr. Turnbull.

Mr. MILLIKIN showed some prints on Carrier's paper mounted on a card along with one on paper recently sensitized. The paper had been kept for four years, and was perfectly white. It printed rapidly, but the finished print showed a want of brilliancy when compared with that on paper recently sensitized. He said, however, that he did not know whether the dullish effect was peculiar to the paper originally, or had come about by change consequent on age.

The attention of the members was then directed to a collection of large photographs of the Yosemite Valley, kindly lent by Mr. J. R. Carphin, and which were hung on the walls; and also some fine enlargements by the Autotype Company, from negatives by Wilson and Burns. The collection was very much admired, and the photographer, whoever he may have been, complimented on the energy and determination to overcome difficulties shown in the production of such large pictures of such almost inaccessible portions of the country.

Votes of thanks were then awarded to Messrs. Neilson, Carphin, and the Chairman, and the meeting adjourned.

### Talk in the Studio.

BERLIN CARDS.—We have received from Mr. R. F. Barnes, of New Cross, a few examples of a novelty in the treatment and "getting up" of card portraits in which the work is exceedingly fine, and the style very effective. All the portraits are simply head and bust, posed and arranged with much skill, and lighted in what is termed the Rembrandt style, but without the exaggerated and violent effects of light and shade often seen in this style. Judicious touching on the negative with lead pencil only serves to secure delicacy without losing natural texture. The special novelty is in the mount, which consists of a chocolate coloured enamelled card, so like the tone of the print that they are scarcely distinguishable, and the result is an effect of quiet richness singularly pleasing.

A PROVINCIAL STUDIO.—We find in a provincial journal a notice of a new studio built at Redcar, a charming sea bathing

place on the Yorkshire coast, which gives pleasant evidence of successful enterprise. The journal in question speaks of the "exertions made by Mr. Hoggard to render his studio second to none in Europe in internal arrangement and completeness. After passing through the avenue of paintings, the visitor finds himself in the reception room, from whence by a small staircase he ascends to the large hall. This grand *salon*, which is fifty-one feet long and eighteen feet broad, is a marvel of elegance, and seems wonderfully adapted to its purpose. Being lighted only from the north side, the "sitter" receives the light in a natural way, and does not show upon his face the war of conflicting shadows which destroy the expression. Around the room are screens and curtains to modify the intensity of the light, and here and there veritable articles of furniture destined to figure in the photographs—such as easy chairs, Davenports, writing desks, and music stands. Here, also, we find cameras of immense capacity, and lenses procured at an enormous cost from the best makers. At one end of this room is the artist's finishing *atelier*, and at the other the developing chamber—both fitted up with all the newest appliances which science can suggest. By another staircase we are conducted below to a nest of rooms, called, respectively, the printing room and the toning room, &c., &c. In the last named chamber, and placed in an immense cistern of water, is a miniature water wheel, whose special duty it is to keep the water of the cistern in motion, so as to render all the photographs placed in it permanent. This arrangement is certainly ingenious, and is, we are informed, truly efficacious. At length we reach the equestrian studio, built for the purpose of taking instantaneous photographs of horses, &c. The whole premises are warmed by hot water."

**TEAR-SPOTS ON SILVERED ALBUMEN PAPER.**—Mr. L. D. Judkins, writing to our Philadelphia contemporary, says:—"The first symptoms of tear-spots on the drying of silvered albumen paper is the oily appearance on the silvered surface while drying, the free surplus silver running down the sheet in small rivulets, then breaking up into small globe-like bodies; and, if left to dry, form what is often called tear-spots, a source of great annoyance to many photographers. If at any time the paper dries as above stated, pin the paper to a board at each corner with copper tacks, and while moist take a tuft of cotton and destroy the small bodies of silver as they form on the surface of the paper by brushing them away. But if the paper has become nearly surface dry, wet the tuft of cotton with the drip on the bottom of the sheet, and moisten the surface of the affected part again; the paper now assumes a smooth surface, and dries free from spots."

**CLEANING PLATES.**—Another correspondent of the same journal says:—"Strong cyanide is the best thing I know of to clean glass plates. Rub both sides with a sponge tied on a stick, then rinse in water, when the glass will be ready for albumenizing if you use that for a substratum. I do not use a substratum, but rub the plates as I take them from the water with whiting, letting it dry on. Plates so prepared will keep any length of time. When wanted for use, rub off the whiting with a *dry* chamois leather, and you will have a clean plate, and one on which the collodion will stick."

**HOW TO CUT PAPER.**—Here is our method of cutting paper. We have two pieces of zinc, the first of which is  $3\frac{3}{8}$  inches, and the second 2 inches wide; take a quarter sheet of paper, lay it on the table, place the larger pattern on one edge and cut off a strip the width of the pattern; lay it on as before, and it will just half cover the remainder. Cut along the edge as before, and the quarter sheet is in three strips  $3\frac{3}{8}$  inches wide; then take the smaller pattern and cut across the strips in the same way, and you have pieces of paper just right for cartes-de-visite. We use a rolling glass cutter which does not go close to the pattern, so the latter are a little smaller than the paper is to be cut. If a cutter is used that will cut the paper as small as the patterns, the latter should be  $3\frac{3}{8}$  and  $2\frac{1}{2}$  inches respectively. The above method gives forty-eight cartes out of a sheet, and is much more convenient than to fold the paper and then cut; it leaves the edges smooth and straight, and does not, besides, break the paper.—*Philadelphia Photographer.*

**HYPOSULPHITE OF SILVER.**—Protoxide of silver has so great an affinity for hyposulphurous acid that it abstracts it from potassa and soda. If oxide of silver be digested with a solution of hyposulphite of soda, a considerable proportion of oxide of silver dissolves, and the liquid, when evaporated, yields crystals of the double hyposulphite of soda and silver. The chloride, bromide, and iodide of silver also dissolve readily in a solution of hyposulphite of soda, and after evaporation the

liquid affords the same crystals of double hyposulphite. The solubility of the chloride, bromide, and iodide of silver is applied in photography to the fixing of the image—that is, to the removal of the compounds of silver from the parts which have not been acted on by light. Solutions of the double hyposulphites, when boiled, give off sulphide of silver, and sulphate of soda is formed. The hyposulphites of silver can be obtained isolated, in the form of a white powder, by pouring a solution of hyposulphite of soda into a solution of nitrate of silver; but the precipitate soon blackens in the light, sulphide of silver being formed.—*Regnault's Chemistry.*

## To Correspondents.

**PAPYRI'S.**—The defects in the pieces of sensitized paper forwarded arise from two different causes. In one the defect is in albumenizing the paper. An air-bubble has formed on the surface on the first contact of the paper with the albumen solution, and so formed the iridescent marking at its edges. The red mottled markings are due, probably, to the use of a small quantity of a somewhat weak solution in sensitizing.

**C. W.**—You will find it wise to learn the metrical system of weights and measures. The formula is, in round numbers, as follows:—  
Distilled water... .. 22 drachms  
Nitrate of silver ... .. 3  
Alcohol ... ..  $5\frac{1}{2}$  "

**W. E.**—See answer to "C. W." above.

**RED HEAD.**—The defects in your prints are due to a variety of causes. In the first place, the negatives are not good; some are thin and foggy, others are hard, and almost all are lacking in definition, either from bad focussing or the sitter moving, and there is slovenly, careless manipulation in all. No. 1 is apparently from a slightly foggy negative, and is not printed sufficiently deeply, hence the weak grey tone. No. 2 is a hard negative; the tone is not bad, but the print is smeared with some mess over the surface. No. 3: the print is not bad, but is a little over-toned, and is also smeared with something. No. 4, the same as last. No. 5 is dirty and out of focus. No. 6, the same. You apparently use some very hard water for rinsing the prints before toning, by which a grey deposit of carbonate or chloride of silver is formed on the print, which interferes with toning. When such a deposit forms, take a clean sponge and pass it over the surface of the print. Your letter was too late for answer in our last.

**G. E. D.**—Old collodion is often very efficient in cleaning plates, but it is very unpleasant and painful to the eyes. Putty powder will remove the stains of which you complain.

**M. G.**—You may varnish your prints if you wish, but the result is not pleasing, and bears no comparison with the effect of enamelling with gelatine and collodion.

**B. F. N.**—The defect of which you complain is in reality a good quality. The sky in the negative should not be so dense as to print white, or the negative will be hard. The slight tint in the print sent will not interfere with the effect of clouds lightly printed in. With suitable cloud negatives it is not important to block out trees and tops of buildings.

**J. L.**—Carbonate of lime (that is, pure chalk) is the best thing you can use for readily neutralizing a solution of chloride of gold without rendering it alkaline. A good toning bath can be made in a quarter of an hour by mixing a little precipitated chalk—to be had of any chemist—with chloride of gold, and then adding warm water. It will be ready for use as soon as it is cold.

**TRO.**—Carpet is not a good thing for the floor of a studio, as it harbours dust. Kamptulicon, or oil-cloth, or linoleum answers very well. Some effective, quiet patterns are to be had in the latter material. Dust in either studio or dark-room is a sad foe to photographic cleanliness.

**N.**—The marks on your negative are due to the gelatine used in your developer. It sometimes happens that thin floating filaments of undissolved gelatine adhere to the collodion film, and prevent the varnish permeating the finished negative. The gelatine is not noticed on the film until its effect is seen after varnishing. On the whole, it is as well to avoid gelatine in the developer.

**PUZZLED.**—A porcelain lined saucepan is not suitable for boiling down a bath. There are frequently minute cracks in the glaze, and hence your solution would come into contact with the iron pan, and cause the blackness you describe. An evaporating dish of Berlin ware is best for the purpose; but you may boil a bath in a Florence flask over a gas burner, if you keep it full and use care.

**G. M. S.**—The loss of glaze in your enamelled prints is due to the softening of the gelatine by the moisture of the gum you used in mounting. To retain the glaze perfectly, the mounting should take place before removing the print from the glass. This plan involves more trouble, however. If you use tolerably stiff paste, or an alcoholic solution of glue, you may avoid much loss of gloss. Several Correspondents in our next.

## PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHIC ENTERPRISE—ORNAMENTATION BY PHOTOGRAPHY—A THIN WATERPROOF PAPER—DRY PLATE DEVELOPMENT.

*Photographic Enterprise.*—A singular instance of photographic enterprise came under our notice a short time since, which amply proves that there are photographers not only fully cognizant of the capabilities of their art, but know, too, how to make the most of them. An announcement put into the first column of the *Times* one morning had the effect of bringing by post the same evening a photographic impression of the whole of the similar notices published on that day. The reproduction was neatly mounted on a card, and sent with a polite request that either it might be returned, or a dozen stamps forwarded in lieu thereof. The negative must, therefore, have been taken, and the impression printed, toned, fixed, washed, and mounted, by the afternoon, in order to be in time for the evening post: and all this work, too, would be done on speculation, in the hope that those interested in the notices of births, deaths, or marriages appearing in that particular edition might be induced to purchase photographic copies of the same. On considering the matter over, one would scarcely imagine the affair would be a paying one, but it is found in practice that the little cards are seldom returned, and that not unfrequently a further demand for copies is made to forward to other relatives. One can hardly assign any reason why people should pay a shilling for a copy of anything that might be purchased for a fourth of the sum, but such is the case, and the recipients are so taken with the novelty of the idea, and neatness and rapidity with which it is carried out, that they send off the stamps long before they have made up their minds what to do with the little card of announcements. There can be no doubt that the little enterprise pays its way, and we congratulate the clever originator of it.

*Ornamentation by Photographs.*—We are glad to see that photographic ornamentation is becoming quite usual upon *menu* cards at the dinner table, upon ball programmes, and other similar trifles. Some time ago we advocated this pretty application of photography, which, if well cultivated, should bring the photographer lots of work to do. Portraits, old tableaux, or tiny little landscapes, form very suitable pictures for the purpose; and when mounted in a proper manner upon a card nicely designed and finished, the result forms a welcome souvenir to keep in remembrance of the auspicious occasion. If it is a dinner given to some great personage, on the occasion of his farewell, or arrival, or what not, there could of course be no more suitable or desirable ornament to the card than an oval medallion portrait of the guest whom all are so desirous of honouring, and in this case the *menu*, upon which much care and taste have usually been bestowed, would have a much better chance of being preserved and taken care of afterwards. At a lawn party or *fête champêtre* some rustic, little scene or fine view, or castle in the neighbourhood, would be a fitting subject; while, again, for balls and routs, some merry-making scene would be in keeping with the occasion. At the banquet given to the Czar the other day at the Crystal Palace, there were photographic portraits of the Imperial guest, as also of the Duke and Duchess of Edinburgh, upon the dinner cards, which were most elaborately executed. Such little portraits as these need cost but very little to produce, supposing one had a moveable back or cameo arrangement to one's camera. In the latter case it is possible to produce six three-quarter inch or inch ovals upon a five by four plate—or, in other words, print seventeen heads—at the cost of a dozen *carte-de-visite* pictures, the little portrait being stamped out afterwards by means of a punch of the requi-

site size, so that the actual cost price would not far exceed half-a-crown or three shillings per hundred. Of course there are the mounting and other matters to be considered, but at any rate the cost of production of such cards would not be greatly increased by the addition of photographs of the kind we mention.

*A Thin Waterproof Paper.*—A thin waterproof tissue for photographic purposes is a desideratum sometimes felt in ordinary manipulations. M. Leon Vidal has for a long time past been seeking a transparent material of the kind for mounting or superposing his heliochromic impressions, for sheets of mica, which were used for the purpose, are rather expensive. At present he employs, we believe, a thin vegetable fabric, made as translucent as possible, and upon this he fits together his transparent, tinted images. As some of our readers may at one time or other stand in need of a cheap waterproof tissue of this kind, they may like to know that tough tissue paper floated for a short time upon the surface of an aqueous solution of shellac in borax, and then dried in the air, will afford them what they desire. And if a coloured waterproof paper is required, then all that is necessary is the addition of a small quantity of aniline colour to the borax.

*Dry Plate Development.*—There is—so an amateur photographer tells us—one thing sadly wanted in dry plate photography to render one perfectly confident of one's results: it is a developing dish of some kind that could be employed at the time of taking the negatives, and which, without being cumbersome, could be used without risk of spoiling one's plates. The old difficulty a tourist experiences, of not knowing what is in his plate box until he arrives home some weeks afterwards and begins to develop, is one that is always urged against the use of dry plates; and if only a practical developing bath—say of orange glass—to slide on and off, could be contrived that would fit closely to the dark slide, out of which the plate might be lowered, much would be done to ease the mind of dry plate workers, and amateurs especially. Concentrated developers might be carried, to be mixed with water wherever a good supply could be procured; and when the development has gone far enough, then the orange glass might be removed, and the further working up of the negative more carefully followed. We give the suggestion for what it is worth.

## AMERICAN CORRESPONDENCE.

“LITTLE DODGES”—OUR NATIONAL EXHIBITION.

*Little Dodges.*—I never went into a photographic establishment yet, I believe, unless I saw or learned of something that was new to me; and I am more likely to see new things in a place of the least pretensions, than in one of a more “*swell*” nature, as you Islanders would say. Some people, too, who practise photography not only because they love it, but because they require bread and butter too, are full of what may be termed “little dodges” or hints and ideas which come useful in the practice of our art. One of this sort is Mr. Robert Benecke, of St. Louis, than whom a better posted photographer does not live. In a letter from him a few days ago, I received a number of useful hints from him. Among other things he “lets out” the following:—

“Another little dodge I have introduced into my practice. The object is to see at one glance whether a plan, map, &c., to be copied, stands parallel with the instrument. It is nothing but a straight board about six or eight inches square, in the centre of which a round stick is fastened perpendicularly. Thus: let the board be of a dark colour, and the stick white. Now hold it or hang it by a string in front of the drawing; let the stick be there where the two diagonals would cross each other. Next point your camera at it. Now if you see in the centre of your ground glass a white circular spot on dark ground, your drawing-board and camera stand correct; if not—that is, if you see the picture of this contrivance too high or too

low—lower or raise your instrument, and shift it until you see no more of the stick but a white spot on black ground. The following sketch will explain it at once.

“Here is another item. It is very desirable often to ascertain the exact amount of nitrate of silver contained in a solution that holds other salts—nitrate of ammonia, for instance—and where, consequently, an actiuv-hydrometer cannot be used. The plan I have adopted is this: take (say) one-half ounce of the solution to be tested, add muriatic acid until all chloride of silver is precipitated (an excess won't hurt\*); take two pieces of filtering paper, both of the same size and kind, put them in a funnel, and pour the chloride, &c., on it; pour also three or four times water on it, to wash out the nitrates. Now, after it has ceased dripping, spread the filters on an old Daguerreotype plate, ferrotype plate, or piece of glass; put it in a hot place, and soon you will have the dry chloride of silver on your filter. Next pull your two filters apart; put the one that has the chloride on one side of the scales, and the other empty filter on the other. Now weigh the chloride. By aid of the following table you can calculate at once how many grains of nitrate of silver there were in the solution.

1	grain chloride of silver	=	1.18	nitrate of silver.
2	“	“	=	2.37
3	“	“	=	3.55
4	“	“	=	4.74
5	“	“	=	5.92
6	“	“	=	7.11
7	“	“	=	8.29
8	“	“	=	9.48
9	“	“	=	10.66
10	“	“	=	11.85

To illustrate this mode by an example, we will suppose we found the chloride contained in one half ounce of the solution to weigh eighteen grains, or double that amount, thirty six grains, in one ounce.

30	grs. chloride of silver	=	35.55	nitrate of silver
6	“	“	=	7.11

42.66 the amount of

nitrate of silver in one ounce of the tested solution.

“Doctors seem to agree now that, in order to get the greatest brilliancy and permanency in silver prints, a short but thorough washing is the plan to be followed. I have some prints now made in 1858, which show no signs of fading yet, and were washed with very little water. They were washed by causing the water to fall on them from a height of ten to twelve feet. I placed them on a board, and by means of a long pole nailed to it, which I lowered from my window, I caught the stream of water on them. The paper would become quite translucent, as if it had been oiled, but would be all right again on drying. With one bucket of water I used to wash three whole size prints. This was rather a tedious way, but some plan could easily be devised by which the same process could be applied on a large scale.

Our National Exhibition is to be held in Chicago in July, The rules and regulations are the same as heretofore, and as a handsome gold medal is offered for the best collection of photographs from England, I trust it will be incentive enough to bring a generous competition from your readers. Another medal is offered for the best collection from France, and still another for the best collection from Germany.—Truly yours,

Philadelphia, May 4th, 1874. EDWARD L. WILSON.

## LANDSCAPE PHOTOGRAPHY: ITS PLEASURES AND PROFIT.

BY W. NEILSON.\*

LET us now—to use a figure strong enough for Hudibras himself—try to have a sniff of the hill air through the nostrils of imagination. We have left the town behind us, with its oppression of smoke, stone, and lime, and exult in the fond belief that nature is waiting expressly for us to take her likeness. We have reached the rural inn, where we intend to lodge for some days. Delightful! A sanded floor, pictures of the four seasons that remind one of the primitive times of Noah and his wife, and everything so nice and clean; all intimating that “life should be spent in calm content.” Thankful to be beyond the reach of gas, we march to bed with honest candles in our hands, led by an old lady who looks like the remnant of an innocent world—the healthy Hebe being left behind to clean our boots. Now we are seated at our first breakfast, with appetites that seem to increase as the viands vanish—six souls in all, as merry as ever was old King Cole. I propose that we should devote the day to “prospecting,” but am immediately put down with a hubbub of exclamations—“We may not have such another glorious day”—“We must have a trial of our plates to see how they work,” &c., &c.; and when a bold man, who is going in for the “wet,” declares that his tent is dying to stretch its legs, it is evident that we are all eager to perform a like operation on ourselves. Having agreed to re-assemble at seven o'clock for that rural symposium, a tea-dinner, four of our number disappear in hot haste, loaded with their traps, whilst a friend joins me in a prospecting tour.
